1. Apache Forrest - org.apache.forrest.plugin.output.inputModule Plugin

Produces properties from an input-module. This is been managed by the heart of this plugin the ModuleGenerator. The generator contacts the input module and gets an iterator of all attribute names. This iterator will be then used to receive the values of the key. Till now we only use a Object to String cast but an input module does not have to return a simple String but can return any object. This may cause ClassCastExceptions for the values.

2. Samples

This section includes links to a number of samples using this plugin. The plugin is intended to be self documenting through these samples. If you require further help please ask on the user mailing list.

- [Properties of the project input module](#) - used in the sitemap like `{properties:content.xdocs}`
- [Properties of the date input module](#) - we cast an object to a string, but the module returns `java.util.Date`. This causes a `ClassCastException`.

Note:

The more samples included here the easier it is for users to understand this plugin. If you can provide additional samples please do so.
