[Phillip Hallam-Baker, Verisign](#)

Abstract:

This specification describes enhancements to SOAP messaging to provide message integrity and confidentiality. The specified mechanisms can be used to accommodate a wide variety of security models and encryption technologies.

This specification also provides a general-purpose mechanism for associating security tokens with message content. No specific type of security token is required, the specification is designed to be extensible (i.e., support multiple security token formats). For example, a client might provide one format for proof of identity and provide another format for proof that they have a particular business certification.

Additionally, this specification describes how to encode binary security tokens, a framework for XML-based tokens, and how to include opaque encrypted keys. It also includes extensibility mechanisms that can be used to further describe the characteristics of the tokens that are included with a message.

171

1 Introduction

172
173
174
175

This OASIS specification is the result of significant new work by the WSS Technical Committee and supersedes the input submissions, Web Service Security (WS-Security) Version 1.0 April 5, 2002 and Web Services Security Addendum Version 1.0 August 18, 2002.

176
177
178
179

This specification proposes a standard set of SOAP [SOAP11, SOAP12] extensions that can be used when building secure Web services to implement message content integrity and confidentiality. This specification refers to this set of extensions and modules as the “Web Services Security: SOAP Message Security” or “WSS: SOAP Message Security”.

180
181
182
183
184
185

This specification is flexible and is designed to be used as the basis for securing Web services within a wide variety of security models including PKI, Kerberos, and SSL. Specifically, this specification provides support for multiple security token formats, multiple trust domains, multiple signature formats, and multiple encryption technologies. The token formats and semantics for using these are defined in the associated profile documents.

186
187
188
189
190
191
192

This specification provides three main mechanisms: ability to send security tokens as part of a message, message integrity, and message confidentiality. These mechanisms by themselves do not provide a complete security solution for Web services. Instead, this specification is a building block that can be used in conjunction with other Web service extensions and higher-level application-specific protocols to accommodate a wide variety of security models and security technologies.

193
194
195
196

These mechanisms can be used independently (e.g., to pass a security token) or in a tightly coupled manner (e.g., signing and encrypting a message or part of a message and providing a security token or token path associated with the keys used for signing and encryption).

197

1.1 Goals and Requirements

198
199
200

The goal of this specification is to enable applications to conduct secure SOAP message exchanges.

201
202
203
204

This specification is intended to provide a flexible set of mechanisms that can be used to construct a range of security protocols; in other words this specification intentionally does not describe explicit fixed security protocols.

205
206
207
208

As with every security protocol, significant efforts must be applied to ensure that security protocols constructed using this specification are not vulnerable to any one of a wide range of attacks. The examples in this specification are meant to illustrate the syntax of these mechanisms and are not intended as examples of combining these mechanisms in secure ways.

209
210
211

The focus of this specification is to describe a single-message security language that provides for message security that may assume an established session, security context and/or policy agreement.

212
213

The requirements to support secure message exchange are listed below.

214

1.1.1 Requirements

215
216

The Web services security language must support a wide variety of security models. The following list identifies the key driving requirements for this specification:

WSS: SOAP Message Security (WS-Security 2004)

Copyright © OASIS Open 2002-2005. All Rights Reserved.

222 1.1.2 Non-Goals

223 The following topics are outside the scope of this document:

- 224
- 225 • Establishing a security context or authentication mechanisms.
- 226 • Key derivation.
- 227 • Advertisement and exchange of security policy.
- 228 • How trust is established or determined.
- 229 • Non-repudiation.
- 230

2 Notations and Terminology

This section specifies the notations, namespaces, and terminology used in this specification.

2.1 Notational Conventions

The keywords "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119.

When describing abstract data models, this specification uses the notational convention used by the XML Infoset. Specifically, abstract property names always appear in square brackets (e.g., [some property]).

When describing concrete XML schemas, this specification uses a convention where each member of an element's [children] or [attributes] property is described using an XPath-like notation (e.g., /x:MyHeader/x:SomeProperty/@value1). The use of {any} indicates the presence of an element wildcard (<xs:any/>). The use of @{any} indicates the presence of an attribute wildcard (<xs:anyAttribute/>).

Readers are presumed to be familiar with the terms in the Internet Security Glossary [GLOS].

2.2 Namespaces

Namespace URIs (of the general form "some-URI") represents some application-dependent or context-dependent URI as defined in RFC 2396 [URI].

This specification is backwardly compatible with version 1.0. This means that URIs and schema elements defined in 1.0 remain unchanged and new schema elements and constants are defined using 1.1 namespaces and URIs.

The XML namespace URIs that MUST be used by implementations of this specification are as follows (note that elements used in this specification are from various namespaces):

```
http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-  
secext-1.0.xsd  
http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-  
utility-1.0.xsd  
http://docs.oasis-open.org/wss/2005/xx/oasis-2005xx-wss-wssecurity-  
secext-1.1.xsd
```

This specification is designed to work with the general SOAP [SOAP11, SOAP12] message structure and message processing model, and should be applicable to any version of SOAP. The current SOAP 1.1 namespace URI is used herein to provide detailed examples, but there is no intention to limit the applicability of this specification to a single version of SOAP.

The namespaces used in this document are shown in the following table (note that for brevity, the examples use the prefixes listed below but do not include the URIs – those listed below are assumed).

2.3 Acronyms and Abbreviations

The following (non-normative) table defines acronyms and abbreviations for this document.

283

284

285

Term	Definition
HMAC	Keyed-Hashing for Message Authentication
SHA-1	Secure Hash Algorithm 1
SOAP	Simple Object Access Protocol
URI	Uniform Resource Identifier
XML	Extensible Markup Language

Formatted Table

2.4 Terminology

Defined below are the basic definitions for the security terminology used in this specification.

287

288

289

290

291

292

293

294

Claim – A *claim* is a declaration made by an entity (e.g. name, identity, key, group, privilege, capability, etc).

Claim Confirmation – A *claim confirmation* is the process of verifying that a claim applies to an entity.

Deleted: 2004.

WSS: SOAP Message Security (WS-Security 2004)
Copyright © OASIS Open 2002-2005. All Rights Reserved.

14 June 2005
Page 10 of 69

295 **Confidentiality** – *Confidentiality* is the property that data is not made available to
296 unauthorized individuals, entities, or processes.

297
298 **Digest** – A *digest* is a cryptographic checksum of an octet stream.

299
300 **Digital Signature** – In this document, digital signature and signature are used
301 interchangeably and have the same meaning.

302
303 **End-To-End Message Level Security** – *End-to-end message level security* is
304 established when a message that traverses multiple applications (one or more SOAP
305 intermediaries) within and between business entities, e.g. companies, divisions and business
306 units, is secure over its full route through and between those business entities. This includes not
307 only messages that are initiated within the entity but also those messages that originate outside
308 the entity, whether they are Web Services or the more traditional messages.

Formatted: Label Embedded,le

309
310 **Integrity** – *Integrity* is the property that data has not been modified.

311
312 **Message Confidentiality** - *Message Confidentiality* is a property of the message and
313 encryption is the mechanism by which this property of the message is provided.

314
315 **Message Integrity** - *Message Integrity* is a property of the message and digital signature is a
316 mechanism by which this property of the message is provided.

317
318 **Signature** - A *signature* is a value computed with a cryptographic algorithm and bound
319 to data in such a way that intended recipients of the data can use the signature to verify that the
320 data has not been altered and/or has originated from the signer of the message, providing
321 message integrity and authentication. The signature can be computed and verified with
322 symmetric key algorithms, where the same key is used for signing and verifying, or with
323 asymmetric key algorithms, where different keys are used for signing and verifying (a private and
324 public key pair are used).

325
326 **Security Token** – A *security token* represents a collection (one or more) of claims.

328
329
330 **Signed Security Token** – A *signed security token* is a security token that is asserted and
331 cryptographically signed by a specific authority (e.g. an X.509 certificate or a Kerberos ticket).

332
333 **Trust** - *Trust* is the characteristic that one entity is willing to rely upon a second entity to execute
334 a set of actions and/or to make set of assertions about a set of subjects and/or scopes.

2.5 Note on Examples

~~The examples which appear in this document are only intended to illustrate the correct syntax of the features being specified. The examples are NOT intended to necessarily represent best practice for implementing any particular security properties.~~

Specifically, the examples are constrained to contain only mechanisms defined in this document. The only reason for this is to avoid requiring the reader to consult other documents merely to understand the examples. It is NOT intended to suggest that the mechanisms illustrated represent best practice or are the strongest available to implement the security properties in question. In particular, mechanisms defined in other Token Profiles are known to be stronger, more efficient and/or generally superior to some of the mechanisms shown in the examples in this document.

3 Message Protection Mechanisms

When securing SOAP messages, various types of threats should be considered. This includes, but is not limited to:

- the message could be modified or read by antagonists or
- an antagonist could send messages to a service that, while well-formed, lack appropriate security claims to warrant processing.
- an antagonist could alter a message to the service which being well formed causes the service to process and respond to the client for an incorrect request.

Formatted: Bulleted + Level: 1 + Aligned at: 0.25" + Tab after: 0.5" + Indent at: 0.5"

Deleted: .

To understand these threats this specification defines a message security model.

3.1 Message Security Model

This document specifies an abstract *message security model* in terms of security tokens combined with digital signatures to protect and authenticate SOAP messages.

Security tokens assert claims and can be used to assert the binding between authentication secrets or keys and security identities. An authority can vouch for or endorse the claims in a security token by using its key to sign or encrypt (it is recommended to use a keyed encryption) the security token thereby enabling the authentication of the claims in the token. An X.509 [X509] certificate, claiming the binding between one's identity and public key, is an example of a signed security token endorsed by the certificate authority. In the absence of endorsement by a third party, the recipient of a security token may choose to accept the claims made in the token based on its trust of the producer of the containing message.

Signatures are used to verify message origin and integrity. Signatures are also used by message producers to demonstrate knowledge of the key, typically from a third party, used to confirm the claims in a security token and thus to bind their identity (and any other claims occurring in the security token) to the messages they create.

It should be noted that this security model, by itself, is subject to multiple security attacks. Refer to the Security Considerations section for additional details.

Where the specification requires that an element be "processed" it means that the element type MUST be recognized to the extent that an appropriate error is returned if the element is not supported.

3.2 Message Protection

Protecting the message content from being disclosed (confidentiality) or modified without detection (integrity) are primary security concerns. This specification provides a means to protect a message by encrypting and/or digitally signing a body, a header, or any combination of them (or parts of them).

Message integrity is provided by XML Signature [XMLSIG] in conjunction with security tokens to ensure that modifications to messages are detected. The integrity mechanisms are designed to support multiple signatures, potentially by multiple SOAP actors/roles, and to be extensible to support additional signature formats.

Page 13 of 69

393 |
 394 | Message confidentiality leverages XML Encryption [XMLENC] in conjunction with security tokens
 395 | to keep portions of a SOAP message confidential. The encryption mechanisms are designed to
 396 | support additional encryption processes and operations by multiple SOAP actors/roles.
 397 |
 398 | This document defines syntax and semantics of signatures within a <wsse:Security> element.
 399 | This document does not specify any signature appearing outside of a <wsse:Security>
 400 | element.

401 3.3 Invalid or Missing Claims

402 | A message recipient SHOULD reject messages containing invalid signatures, messages missing
 403 | necessary claims or messages whose claims have unacceptable values. Such messages are
 404 | unauthorized (or malformed). This specification provides a flexible way for the message producer
 405 | to make a claim about the security properties by associating zero or more security tokens with the
 406 | message. An example of a security claim is the identity of the producer; the producer can claim
 407 | that he is Bob, known as an employee of some company, and therefore he has the right to send
 408 | the message.

409 3.4 Example

410 | The following example illustrates the use of a custom security token and associated signature.
 411 | The token contains base64 encoded binary data conveying a symmetric key which, we assume,
 412 | can be properly authenticated by the recipient. The message producer uses the symmetric key
 413 | with an HMAC signing algorithm to sign the message. The message receiver uses its knowledge
 414 | of the shared secret to repeat the HMAC key calculation which it uses to validate the signature
 415 | and in the process confirm that the message was authored by the claimed user identity.

```

456 | (028) </S11:Body>
457 | (029) </S11:Envelope>

```

Formatted: Polish

458
459 The first two lines start the SOAP envelope. Line (003) begins the headers that are associated
460 with this SOAP message.

461
462 Line (004) starts the <wsse:Security> header defined in this specification. This header
463 contains security information for an intended recipient. This element continues until line (024).

464
465 Lines (005) to (007) specify a custom token that is associated with the message. In this case, it
466 uses an externally defined custom token format.

467
468 Lines (008) to (023) specify a digital signature. This signature ensures the integrity of the signed
469 elements. The signature uses the XML Signature specification identified by the ds namespace
470 declaration in Line (002).

471
472 Lines (009) to (016) describe what is being signed and the type of canonicalization being used.

Deleted:

473
474 Line (010) specifies how to canonicalize (normalize) the data that is being signed. Lines (012) to
475 (015) select the elements that are signed and how to digest them. Specifically, line (012)
476 indicates that the <S11:Body> element is signed. In this example only the message body is
477 signed; typically all critical elements of the message are included in the signature (see the
478 Extended Example below).

479
480 Line (017) specifies the signature value of the canonicalized form of the data that is being signed
481 as defined in the XML Signature specification.

482
483 Lines (018) to (022) provides information, partial or complete, as to where to find the security
484 token associated with this signature. Specifically, lines (019) to (021) indicate that the security
485 token can be found at (pulled from) the specified URL.

486
487 Lines (026) to (028) contain the body (payload) of the SOAP message.

489

4 ID References

490

There are many motivations for referencing other message elements such as signature references or correlating signatures to security tokens. For this reason, this specification defines the `wsu:Id` attribute so that recipients need not understand the full schema of the message for processing of the security elements. That is, they need only "know" that the `wsu:Id` attribute represents a schema type of ID which is used to reference elements. However, because some key schemas used by this specification don't allow attribute extensibility (namely XML Signature and XML Encryption), this specification also allows use of their local ID attributes in addition to the `wsu:Id` attribute. As a consequence, when trying to locate an element referenced in a signature, the following attributes are considered:

491

492

493

494

495

496

497

498

499

500

501

502

503

504

505

506

- Local ID attributes on XML Signature elements
- Local ID attributes on XML Encryption elements
- Global `wsu:Id` attributes (described below) on elements

Formatted: Bulleted + Level: 1 + Aligned at: 0.25" + Tab after: 0.5" + Indent at: 0.5"

Formatted: Font: Courier New

In addition, when signing a part of an envelope such as the body, it is RECOMMENDED that an ID reference is used instead of a more general transformation, especially XPath [XPATH]. This is to simplify processing.

507

4.1 Id Attribute

508

509

510

511

512

513

514

515

There are many situations where elements within SOAP messages need to be referenced. For example, when signing a SOAP message, selected elements are included in the scope of the signature. XML Schema Part 2 [XMLSCHEMA] provides several built-in data types that may be used for identifying and referencing elements, but their use requires that consumers of the SOAP message either have or must be able to obtain the schemas where the identity or reference mechanisms are defined. In some circumstances, for example, intermediaries, this can be problematic and not desirable.

516

517

518

519

520

Consequently a mechanism is required for identifying and referencing elements, based on the SOAP foundation, which does not rely upon complete schema knowledge of the context in which an element is used. This functionality can be integrated into SOAP processors so that elements can be identified and referred to without dynamic schema discovery and processing.

521

522

523

This section specifies a namespace-qualified global attribute for identifying an element which can be applied to any element that either allows arbitrary attributes or specifically allows a particular attribute.

524

4.2 Id Schema

525

526

527

528

529

530

531

532

533

To simplify the processing for intermediaries and recipients, a common attribute is defined for identifying an element. This attribute utilizes the XML Schema ID type and specifies a common attribute for indicating this information for elements.

The syntax for this attribute is as follows:

```
<anyElement wsu:Id="...">...</anyElement>
```

The following describes the attribute illustrated above:

`.../@wsu:Id`

WSS: SOAP Message Security (WS-Security 2004)

14 June 2005

Page 16 of 69

Formatted: Font: 10 pt

Deleted: 15 March 2004

Formatted: Font: 10 pt

Deleted: 2004.

534 This attribute, defined as type `xsd:ID`, provides a well-known attribute for specifying the
535 local ID of an element.

536 Two `wsu:Id` attributes within an XML document MUST NOT have the same value.
537 Implementations MAY rely on XML Schema validation to provide rudimentary enforcement for
538 intra-document uniqueness. However, applications SHOULD NOT rely on schema validation
539 alone to enforce uniqueness.

540 |
541 This specification does not specify how this attribute will be used and it is expected that other
542 specifications MAY add additional semantics (or restrictions) for their usage of this attribute.
543 The following example illustrates use of this attribute to identify an element:

```
544 |  
545 | <x:myElement wsu:Id="ID1" xmlns:x="..."  
546 |     xmlns:wsu="..." />
```

547 |
548 Conformant processors that do support XML Schema MUST treat this attribute as if it was
549 defined using a global attribute declaration.

550 |
551 Conformant processors that do not support dynamic XML Schema or DTDs discovery and
552 processing are strongly encouraged to integrate this attribute definition into their parsers. That is,
553 to treat this attribute information item as if its PSVI has a [type definition] which {target
554 namespace} is "<http://www.w3.org/2001/XMLSchema>" and which {type} is "ID." Doing so
555 allows the processor to inherently know *how* to process the attribute without having to locate and
556 process the associated schema. Specifically, implementations MAY support the value of the
557 `wsu:Id` as the valid identifier for use as an XPointer [XPointer] shorthand pointer for
558 interoperability with XML Signature references.

559

5 Security Header

560
561
562
563
564
565
566

The `<wsse:Security>` header block provides a mechanism for attaching security-related information targeted at a specific recipient in the form of a [SOAP actor/role](#). This may be either the ultimate recipient of the message or an intermediary. Consequently, elements of this type may be present multiple times in a SOAP message. An active intermediary on the message path MAY add one or more new sub-elements to an existing `<wsse:Security>` header block if they are targeted for its SOAP node or it MAY add one or more new headers for additional targets.

Deleted: SOAP

567
568
569
570
571
572
573
574
575

As stated, a message MAY have multiple `<wsse:Security>` header blocks if they are targeted for separate recipients. However, only one `<wsse:Security>` header block MAY omit the `S11:actor` or `S12:role` attributes. Two `<wsse:Security>` header blocks MUST NOT have the same value for `S11:actor` or `S12:role`. Message security information targeted for different recipients MUST appear in different `<wsse:Security>` header blocks. This is due to potential processing order issues (e.g. due to possible header re-ordering). The `<wsse:Security>` header block without a specified `S11:actor` or `S12:role` MAY be processed by anyone, but MUST NOT be removed prior to the final destination or endpoint.

Deleted:

Formatted: Font: Courier New

Formatted: Font: Courier New

576
577
578
579
580
581
582
583

As elements are added to a `<wsse:Security>` header block, they SHOULD be prepended to the existing elements. As such, the `<wsse:Security>` header block represents the signing and encryption steps the message producer took to create the message. This prepending rule ensures that the receiving application can process sub-elements in the order they appear in the `<wsse:Security>` header block, because there will be no forward dependency among the sub-elements. Note that this specification does not impose any specific order of processing the sub-elements. The receiving application can use whatever order is required.

584
585
586
587

When a sub-element refers to a key carried in another sub-element (for example, a signature sub-element that refers to a binary security token sub-element that contains the X.509 certificate used for the signature), the key-bearing element SHOULD be ordered to precede the key-using Element:

```
<S11:Envelope>
  <S11:Header>
    ...
    <wsse:Security S11:actor="..." S11:mustUnderstand="...">
      ...
    </wsse:Security>
    ...
  </S11:Header>
  ...
</S11:Envelope>
```

588

654

/wsse:Security/@S12:role

This attribute allows a specific SOAP 1.2 [SOAP12] role to be identified. This attribute is optional; however, no two instances of the header block may omit a role or specify the same role.

/wsse:Security/@S11:mustUnderstand

This SOAP 1.1 [SPOAP11] attribute is used to indicate whether a header entry is mandatory or optional for the recipient to process. The value of the mustUnderstand attribute is either "1" or "0". The absence of the SOAP mustUnderstand attribute is semantically equivalent to its presence with the value "0".

/wsse:Security/@S12:mustUnderstand

This SOAP 1.2 [SPOAP12] attribute is used to indicate whether a header entry is mandatory or optional for the recipient to process. The value of the mustUnderstand attribute is either "true" or "false". The absence of the SOAP mustUnderstand attribute is semantically equivalent to its presence with the value "false".

/wsse:Security/{any}

This is an extensibility mechanism to allow different (extensible) types of security information, based on a schema, to be passed. Unrecognized elements SHOULD cause a fault.

/wsse:Security/@{any}

This is an extensibility mechanism to allow additional attributes, based on schemas, to be added to the header. Unrecognized attributes SHOULD cause a fault.

All compliant implementations MUST be able to process a <wsse:Security> element.

All compliant implementations MUST declare which profiles they support and MUST be able to process a <wsse:Security> element including any sub-elements which may be defined by that profile. It is RECOMMENDED that undefined elements within the <wsse:Security> header not be processed.

The next few sections outline elements that are expected to be used within a <wsse:Security> header.

When a <wsse:Security> header includes a mustUnderstand="true" attribute:

- The receiver MUST generate a SOAP fault if does not implement the WSS: SOAP Message Security specification corresponding to the namespace. Implementation means ability to interpret the schema as well as follow the required processing rules specified in WSS: SOAP Message Security.
- The receiver **MUST** generate a fault if unable to interpret or process security tokens contained in the <wsse:Security> header block according to the corresponding WSS: SOAP Message Security token profiles.
- Receivers MAY ignore elements or extensions within the <wsse:Security> element, based on local security policy.

655

6 Security Tokens

656
657

This chapter specifies some different types of security tokens and how they are attached to messages.

658

6.1 Attaching Security Tokens

659
660
661
662

This specification defines the `<wsse:Security>` header as a mechanism for conveying security information with and about a SOAP message. This header is, by design, extensible to support many types of security information.

663
664

For security tokens based on XML, the extensibility of the `<wsse:Security>` header allows for these security tokens to be directly inserted into the header.

665

6.1.1 Processing Rules

666
667
668
669

This specification describes the processing rules for using and processing XML Signature and XML Encryption. These rules MUST be followed when using any type of security token. Note that if signature or encryption is used in conjunction with security tokens, they MUST be used in a way that conforms to the processing rules defined by this specification.

670

6.1.2 Subject Confirmation

671
672
673

This specification does not dictate if and how claim confirmation must be done; however, it does define how signatures may be used and associated with security tokens (by referencing the security tokens from the signature) as a form of claim confirmation.

674

6.2 User Name Token

675

6.2.1 Usernames

676
677
678

The `<wsse:UsernameToken>` element is introduced as a way of providing a username. This element is optionally included in the `<wsse:Security>` header. The following illustrates the syntax of this element:

679
680
681
682

```
<wsse:UsernameToken wsu:Id="...">
  <wsse:Username>...</wsse:Username>
</wsse:UsernameToken>
```

683

The following describes the attributes and elements listed in the example above:

684

/wsse:UsernameToken

685

This element is used to represent a claimed identity.

686

/wsse:UsernameToken/@wsu:Id

687

A string label for this security token. The `wsu:Id` allow for an open attribute model.

688

/wsse:UsernameToken/wsse:Username

689

This required element specifies the claimed identity.

690

691

692

693

694

695 /wsse:UsernameToken/wsse:Username/{any}
696 This is an extensibility mechanism to allow additional attributes, based on schemas, to be
697 added to the <wsse:Username> element.

698 |
699 /wsse:UsernameToken/{any}
700 This is an extensibility mechanism to allow different (extensible) types of security
701 information, based on a schema, to be passed. Unrecognized elements SHOULD cause
702 a fault.

703 |
704 /wsse:UsernameToken/{any}
705 This is an extensibility mechanism to allow additional attributes, based on schemas, to be
706 added to the <wsse:UsernameToken> element. Unrecognized attributes SHOULD
707 cause a fault.

708 |
709 All compliant implementations MUST be able to process a <wsse:UsernameToken> element.
710 The following illustrates the use of this:

```
711  
712 <S11:Envelope xmlns:S11="..." xmlns:wsse="...">  
713   <S11:Header>  
714     ...  
715     <wsse:Security>  
716       <wsse:UsernameToken>  
717         <wsse:Username>Zoe</wsse:Username>  
718       </wsse:UsernameToken>  
719     </wsse:Security>  
720     ...  
721   </S11:Header>  
722   ...  
723 </S11:Envelope>  
724
```

Formatted: German (Germany)

725 6.3 Binary Security Tokens

726 6.3.1 Attaching Security Tokens

727 For binary-formatted security tokens, this specification provides a
728 <wsse:BinarySecurityToken> element that can be included in the <wsse:Security>
729 header block.

730 6.3.2 Encoding Binary Security Tokens

731 Binary security tokens (e.g., X.509 certificates and Kerberos [KERBEROS] tickets) or other non-
732 XML formats require a special encoding format for inclusion. This section describes a basic
733 framework for using binary security tokens. Subsequent specifications MUST describe the rules
734 for creating and processing specific binary security token formats.

735 |
736 The <wsse:BinarySecurityToken> element defines two attributes that are used to interpret
737 it. The ValueType attribute indicates what the security token is, for example, a Kerberos ticket.
738 The EncodingType tells how the security token is encoded, for example Base64Binary.
739 The following is an overview of the syntax:

```
740  
741 <wsse:BinarySecurityToken wsu:Id=...  
742   EncodingType=...  
743   ValueType=.../>
```

765
766

The following describes the attributes and elements listed in the example above:

/wsse:BinarySecurityToken

This element is used to include a binary-encoded security token.

/wsse:BinarySecurityToken/@wsu:Id

An optional string label for this security token.

/wsse:BinarySecurityToken/@ValueType

The `ValueType` attribute is used to indicate the "value space" of the encoded binary data (e.g. an X.509 certificate). The `ValueType` attribute allows a URI that defines the value type and space of the encoded binary data. Subsequent specifications **MUST** define the `ValueType` value for the tokens that they define. The usage of `ValueType` is **RECOMMENDED**.

/wsse:BinarySecurityToken/@EncodingType

The `EncodingType` attribute is used to indicate, using a URI, the encoding format of the binary data (e.g., `base64` encoded). A new attribute is introduced, as there are issues with the current schema validation tools that make derivations of mixed simple and complex types difficult within XML Schema. The `EncodingType` attribute is interpreted to indicate the encoding format of the element. The following encoding formats are pre-defined (note that the URI fragments are relative to the URI for this specification):

URI	Description
#Base64Binary (default)	XML Schema base 64 encoding

Formatted Table

767
768
769
770
771
772
773

/wsse:BinarySecurityToken/@{any}

This is an extensibility mechanism to allow additional attributes, based on schemas, to be added.

All compliant implementations **MUST** be able to process a `<wsse:BinarySecurityToken>` element.

Deleted: ¶
When a `<wsse:BinarySecurityToken>` is included in a signature—that is, it is referenced from a `<ds:Signature>` element—care should be taken so that the canonicalization algorithm (e.g., Exclusive XML Canonicalization [EXC-C14N]) does not allow unauthorized replacement of namespace prefixes of the QNames used in the attribute or element values. In particular, it is **RECOMMENDED** that these namespace prefixes be declared within the `<wsse:BinarySecurityToken>` element if this token does not carry the validating key (and consequently it is not cryptographically bound to the signature).

6.4 XML Tokens

775
776

This section presents framework for using XML-based security tokens. Profile specifications describe rules and processes for specific XML-based security token formats.

6.5 EncryptedData Token

778
779
780
781
782
783
784
785
786

In certain cases it is desirable that the token included in the `<wsse:Security>` header be encrypted for the recipient processing role. In such a case the `<xenc:EncryptedData>` element **MAY** be used to contain a security token and included in the `<wsse:Security>` header. That is this specification defines the usage of `<xenc:EncryptedData>` to encrypt security tokens contained in `<wsse:Security>` header.

It should be noted that token references are not made to the `<xenc:EncryptedData>` element, but instead to the token represented by the clear-text, once the `<xenc:EncryptedData>` element has been processed (decrypted). Such references utilize the token profile for the

Formatted: Font: 10 pt

Deleted: 15 March 2004

Formatted: Font: 10 pt

Deleted: 2004.

787 contained token. i.e., <xenc:EncryptedData> SHOULD NOT include an XML Id for
788 referencing the contained security token.

789 All <xenc:EncryptedData> tokens SHOULD either have an embedded encryption key or
790 should be referenced by a separate encryption key.
791 When a <xenc:EncryptedData> token is processed, it is replaced in the message info set with
792 its decrypted form.

Formatted: Heading 2, H2, h2, Level 2 Topic Heading

794 6.6 Identifying and Referencing Security Tokens

795 This specification also defines multiple mechanisms for identifying and referencing security
796 tokens using the wsu:Id attribute and the <wsse:SecurityTokenReference> element (as
797 well as some additional mechanisms). Please refer to the specific profile documents for the
798 appropriate reference mechanism. However, specific extensions MAY be made to the
799 <wsse:SecurityTokenReference> element.

801

7 Token References

802

This chapter discusses and defines mechanisms for referencing security tokens and other key bearing elements.

803

Formatted: Font: Helvetica

Formatted: Text,t

804

7.1 SecurityTokenReference Element

805

Digital signature and encryption operations require that a key be specified. For various reasons, the element containing the key in question may be located elsewhere in the message or completely outside the message. The <wsse:SecurityTokenReference> element provides an extensible mechanism for referencing security tokens and other key bearing elements.

806

807

808

809

810

The <wsse:SecurityTokenReference> element provides an open content model for referencing key bearing elements because not all of them support a common reference pattern. Similarly, some have closed schemas and define their own reference mechanisms. The open content model allows appropriate reference mechanisms to be used.

811

812

813

814

815

If a <wsse:SecurityTokenReference> is used outside of the security header processing block the meaning of the response and/or processing rules of the resulting references MUST be specified by the containing element and are out of scope of this specification. The following illustrates the syntax of this element:

816

817

818

819

820

```
<wsse:SecurityTokenReference wsu:Id="...">
  ...
</wsse:SecurityTokenReference>
```

821

822

823

824

The following describes the elements defined above:

825

826

/wsse:SecurityTokenReference

This element provides a reference to a security token.

827

828

829

/wsse:SecurityTokenReference/@wsu:Id

A string label for this security token reference which names the reference. This attribute does not indicate the ID of what is being referenced, that SHOULD be done using a fragment URI in a <wsse:Reference> element within the <wsse:SecurityTokenReference> element.

830

831

832

833

834

835

/wsse:SecurityTokenReference/@wsse:TokenType

This optional attribute is used to identify, by URI, the type of the referenced token. This specification recommends that token specific profiles define appropriate token type identifying URI values, and that these same profiles require that these values be specified in the profile defined reference forms.

836

837

838

839

840

841

When a TokenType attribute is specified in conjunction with a wsse:KeyIdentifier/@ValueType attribute or a wsse:Reference/@ValueType attribute that indicates the type of the referenced token, the security token type identified by the TokenType attribute MUST be consistent with the security token type identified by the ValueType attribute.

842

843

844

846 |
847 | /wsse:SecurityTokenReference/@wsse:Usage
848 | This optional attribute is used to type the usage of the
849 | <wsse:SecurityTokenReference>. Usages are specified using URIs and multiple
850 | usages MAY be specified using XML list semantics. No usages are defined by this
851 | specification.
852 |
853 | /wsse:SecurityTokenReference/{any}
854 | This is an extensibility mechanism to allow different (extensible) types of security
855 | references, based on a schema, to be passed. Unrecognized elements SHOULD cause a
856 | fault.
857 |
858 | /wsse:SecurityTokenReference/@{any}
859 | This is an extensibility mechanism to allow additional attributes, based on schemas, to be
860 | added to the header. Unrecognized attributes SHOULD cause a fault.
861 |
862 | All compliant implementations MUST be able to process a
863 | <wsse:SecurityTokenReference> element.
864 |
865 | This element can also be used as a direct child element of <ds:KeyInfo> to indicate a hint to
866 | retrieve the key information from a security token placed somewhere else. In particular, it is
867 | RECOMMENDED, when using XML Signature and XML Encryption, that a
868 | <wsse:SecurityTokenReference> element be placed inside a <ds:KeyInfo> to reference
869 | the security token used for the signature or encryption.
870 |
871 | There are several challenges that implementations face when trying to interoperate. Processing
872 | the IDs and references requires the recipient to *understand* the schema. This may be an
873 | expensive task and in the general case impossible as there is no way to know the "schema
874 | location" for a specific namespace URI. As well, the primary goal of a reference is to uniquely
875 | identify the desired token. ID references are, by definition, unique by XML. However, other
876 | mechanisms such as "principal name" are not required to be unique and therefore such
877 | references may be not unique.
878 |
879 | The following list provides a list of the specific reference mechanisms defined in WSS: SOAP
880 | Message Security in preferred order (i.e., most specific to least specific):
881 |
882 | • **Direct References** – This allows references to included tokens using URI fragments and
883 | external tokens using full URIs.
884 | • **Key Identifiers** – This allows tokens to be referenced using an opaque value that
885 | represents the token (defined by token type/profile).
886 | • **Key Names** – This allows tokens to be referenced using a string that matches an identity
887 | assertion within the security token. This is a subset match and may result in multiple
888 | security tokens that match the specified name.
889 | • **Embedded References** - This allows tokens to be embedded (as opposed to a pointer
890 | to a token that resides elsewhere).

Formatted: Default Paragraph Font

Formatted: Default Paragraph Font,
Font: Courier New

891 | 7.2 Direct References

892 | The <wsse:Reference> element provides an extensible mechanism for directly referencing
893 | security tokens using URIs.

894 |
895 | The following illustrates the syntax of this element:

```
<wsse:SecurityTokenReference wsu:Id="...">
  <wsse:Reference URI="..." ValueType="..." />
</wsse:SecurityTokenReference>
```

The following describes the elements defined above:

/wsse:SecurityTokenReference/wsse:Reference
This element is used to identify an abstract URI location for locating a security token.

/wsse:SecurityTokenReference/wsse:Reference/@URI
This optional attribute specifies an abstract URI for where to find a security token. If a fragment is specified, then it indicates the local ID of the token being referenced.

/wsse:SecurityTokenReference/wsse:Reference/@ValueType
This optional attribute specifies a URI that is used to identify the *type* of token being referenced. This specification does not define any processing rules around the usage of this attribute, however, specifications for individual token types MAY define specific processing rules and semantics around the value of the URI and how it SHALL be interpreted. If this attribute is not present, the URI MUST be processed as a normal URI. The use of this attribute to identify the type of the referenced security token is deprecated. Profiles which require or recommend the use of this attribute to identify the type of the referenced security token SHOULD evolve to require or recommend the use of the wsse:SecurityTokenReference/@wsse:TokenType attribute to identify the type of the referenced token.

Formatted: ElementDesc

Deleted: usage

Deleted: ValueType

Formatted: Font: Helvetica

Deleted: RECOMMENDED for references with local URIs

Formatted: Font: (Default) Times New Roman, 12 pt

/wsse:SecurityTokenReference/wsse:Reference/{any}
This is an extensibility mechanism to allow different (extensible) types of security references, based on a schema, to be passed. Unrecognized elements SHOULD cause a fault.

/wsse:SecurityTokenReference/wsse:Reference/@{any}
This is an extensibility mechanism to allow additional attributes, based on schemas, to be added to the header. Unrecognized attributes SHOULD cause a fault.

The following illustrates the use of this element:

```
<wsse:SecurityTokenReference
  xmlns:wsse="...">
  <wsse:Reference
    URI="http://www.fabrikam123.com/tokens/Zoe"/>
</wsse:SecurityTokenReference>
```

7.3 Key Identifiers

Alternatively, if a direct reference is not used, then it is RECOMMENDED to use a key identifier to specify/reference a security token instead of a `<ds:KeyName>`. A key identifier is a value that can be used to uniquely identify a security token (e.g. a hash of the important elements of the security token). The exact value type and generation algorithm varies by security token type (and sometimes by the data within the token), Consequently, the values and algorithms are described in the token-specific profiles rather than this specification.

Deleted: KeyIdentifier

Formatted: Font: 10 pt

Deleted: 15 March 2004

Formatted: Font: 10 pt

Deleted: 2004.

946 The <wsse:KeyIdentifier> element SHALL be placed in the
 947 <wsse:SecurityTokenReference> element to reference a token using an identifier. This
 948 element SHOULD be used for all key identifiers.

949
 950 The processing model assumes that the key identifier for a security token is constant.
 951 Consequently, processing a key identifier is simply looking for a security token whose key
 952 identifier matches a given specified constant. The <wsse:KeyIdentifier> element is only
 953 allowed inside a <wsse:SecurityTokenReference> element

954 The following is an overview of the syntax:

```

955 <wsse:SecurityTokenReference>
956   <wsse:KeyIdentifier wsu:Id="..."
957                       ValueType="..."
958                       EncodingType="...">
959     ...
960   </wsse:KeyIdentifier>
961 </wsse:SecurityTokenReference>
  
```

962
 963 The following describes the attributes and elements listed in the example above:

964
 965 /wsse:SecurityTokenReference/wsse:KeyIdentifier

966 This element is used to include a binary-encoded key identifier.

Formatted: Font: Italic

Formatted: Font: Italic

967
 968
 969 /wsse:SecurityTokenReference/wsse:KeyIdentifier/@wsu:Id

970 An optional string label for this identifier.

971
 972 /wsse:SecurityTokenReference/wsse:KeyIdentifier/@ValueType

973 The optional ValueType attribute is used to indicate the type of KeyIdentifier being
 974 used. This specification defines one ValueType that can be applied to all token types.

975 Each specific token profile specifies the KeyIdentifier types that may be used to
 976 refer to tokens of that type. It also specifies the critical semantics of the identifier, such as
 977 whether the KeyIdentifier is unique to the key or the token. If no value is specified
 978 then the key identifier will be interpreted in an application-specific manner. This URI
 979 fragment is relative to a base URI of
 980 <http://docs.oasis-open.org/wss/2005/xx/oasis-2005xx-wss-soap->
 981 [message-security-1.1](http://docs.oasis-open.org/wss/2005/xx/oasis-2005xx-wss-soap-message-security-1.1)
 982

URI	Description
<u>http://docs.oasis-open.org/wss/2005/xx/oasis-2005xx-wss-soap-message-security-1.1#ThumbprintSHA1</u>	<u>If the security token type that the Security Token Reference refers to already contains a representation for the thumbprint, the value obtained from the token MAY be used. If the token does not contain a representation of a thumbprint, then the value of the KeyIdentifier MUST be the SHA1 of the raw octets which would be encoded within the security token element were it to be included.</u>

983
 984 /wsse:SecurityTokenReference/wsse:KeyIdentifier/@EncodingType

985 The optional EncodingType attribute is used to indicate, using a URI, the encoding
 986 format of the KeyIdentifier (#Base64Binary). This specification defines the

987 [EncodingType URI values appearing in the following table. A token specific profile MAY](#)
 988 [define additional token specific EncodingType URI values. A KeyIdentifier MUST include](#)
 989 [an EncodingType attribute when its ValueType is not sufficient to identify its encoding](#)
 990 [type.](#) The base values defined in this specification are used (Note that URI fragments are
 991 relative to this document's URI):
 992

URI	Description
#Base64Binary	XML Schema base 64 encoding

← Formatted Table

Deleted: (default)

993
 994 `/wsse:SecurityTokenReference/wsse:KeyIdentifier/{any}`
 995 This is an extensibility mechanism to allow additional attributes, based on schemas, to be
 996 added.

997 7.4 Embedded References

998 In some cases a reference may be to an embedded token (as opposed to a pointer to a token
 999 that resides elsewhere). To do this, the `<wsse:Embedded>` element is specified within a
 1000 `<wsse:SecurityTokenReference>` element. [The `<wsse:Embedded>` element is only](#)
 1001 [allowed inside a `<wsse:SecurityTokenReference>` element.](#)

1002 The following is an overview of the syntax:

```
1003 <wsse:SecurityTokenReference>
1004   <wsse:Embedded wsu:Id="...">
1005     ...
1006   </wsse:Embedded>
1007 </wsse:SecurityTokenReference>
```

1009 The following describes the attributes and elements listed in the example above:

1010 `/wsse:SecurityTokenReference/wsse:Embedded`

1011 This element is used to embed a token directly within a reference (that is, to create a
 1012 *local* or *literal* reference).

1013 `/wsse:SecurityTokenReference/wsse:Embedded/@wsu:Id`

1014 An optional string label for this element. This allows this embedded token to be
 1015 referenced by a signature or encryption.

1016 `/wsse:SecurityTokenReference/wsse:Embedded/{any}`

1017 This is an extensibility mechanism to allow any security token, based on schemas, to be
 1018 embedded. Unrecognized elements SHOULD cause a fault.

1019 `/wsse:SecurityTokenReference/wsse:Embedded/{any}`

1020 This is an extensibility mechanism to allow additional attributes, based on schemas, to be
 1021 added. Unrecognized attributes SHOULD cause a fault.

1022 The following example illustrates embedding a SAML assertion:

```
1023 <S11:Envelope xmlns:S11="..." xmlns:wsse="..." xmlns:wsu="...">
1024   <S11:Header>
1025     <wsse:Security>
1026       ...
1027     </wsse:SecurityTokenReference>
```

Formatted: Font: 10 pt

Deleted: 2004.

1035
1036
1037
1038
1039
1040
1041
1042
1043
1044
1045

```
<wsse:Embedded wsu:Id="tok1">
  <saml:Assertion xmlns:saml="...">
    ...
  </saml:Assertion>
</wsse:Embedded>
</wsse:SecurityTokenReference>
...
<wsse:Security>
</S11:Header>
...
</S11:Envelope>
```

1046 **7.5 ds:KeyInfo**

1047 The <ds:KeyInfo> element (from XML Signature) can be used for carrying the key information
1048 and is allowed for different key types and for future extensibility. However, in this specification,
1049 the use of <wsse:BinarySecurityToken> is the RECOMMENDED mechanism to carry key
1050 material if the key type contains binary data. Please refer to the specific profile documents for the
1051 appropriate way to carry key material.

1052 | The following example illustrates use of this element to fetch a named key:

```
<ds:KeyInfo Id="..." xmlns:ds="http://www.w3.org/2000/09/xmldsig#">
  <ds:KeyName>CN=Hiroshi Maruyama, C=JP</ds:KeyName>
</ds:KeyInfo>
```

1058 **7.6 Key Names**

1059 It is strongly RECOMMENDED to use <wsse:KeyIdentifier> elements. However, if key
1060 names are used, then it is strongly RECOMMENDED that <ds:KeyName> elements conform to
1061 the attribute names in section 2.3 of RFC 2253 (this is recommended by XML Signature for
1062 <ds:X509SubjectName>) for interoperability.

1063 | Additionally, e-mail addresses, SHOULD conform to RFC 822:

```
EmailAddress=ckaler@microsoft.com
```

1066 **7.7 Encrypted Key reference**

1067 In certain cases, an <xenc:EncryptedKey> element MAY be used to carry key material
1068 encrypted for the recipient's key. This key material is henceforth referred to as EncryptedKey.

1069 | The EncryptedKey MAY be used to perform other cryptographic operations within the same
1070 message, such as signatures. The EncryptedKey MAY also be used for performing
1071 cryptographic operations in subsequent messages exchanged by the two parties. Two
1072 mechanisms are defined for referencing the EncryptedKey.

1073 | When referencing the EncryptedKey within the same message that contains the
1074 <xenc:EncryptedKey> element, the <ds:KeyInfo> element of the referencing construct
1075 MUST contain a <wsse:SecurityTokenReference>. The
1076 <wsse:SecurityTokenReference> element MUST contain a <wsse:Reference> element.

1077 | The URI attribute value of the <wsse:Reference> element MUST be set to the value of the ID
1078 attribute of the referenced <xenc:EncryptedKey> element that contains the EncryptedKey.

Formatted: Font: 10 pt
Deleted: 15 March 2004
Formatted: Font: 10 pt
Deleted: 2004.

1082 When referencing the EncryptedKey in a message that does not contain the
1083 <xenc:EncryptedKey> element, the <ds:KeyInfo> element of the referencing construct
1084 MUST contain a <wsse:SecurityTokenReference>. The
1085 <wsse:SecurityTokenReference> element MUST contain a <wsse:KeyIdentifier>
1086 element. The EncodingType attribute SHOULD be set to #Base64Binary. Other encoding
1087 types MAY be specified if agreed on by all parties. The ValueType attribute MUST be set to
1088 http://docs.oasis-open.org/wss/2005/xx/oasis-2005xx-wss-soap-message-
1089 security-1.1#EncryptedKey. The identifier for a <xenc:EncryptedKey> token is defined
1090 as the SHA1 of the raw (pre-base64 encoding) octets specified in the <xenc:CipherValue>
1091 element of the referenced <xenc:EncryptedKey> token. This value is encoded as indicated in
1092 the KeyIdentifier reference. The ValueType attribute MUST be set to
1093 http://docs.oasis-open.org/wss/2005/xx/oasis-2005xx-wss-soap-message-
1094 security-1.1#EncryptedKeySHA1

Formatted: Font: 10 pt

Deleted: 2004.

1095

8 Signatures

1096

Message producers may want to enable message recipients to determine whether a message was altered in transit and to verify that the claims in a particular security token apply to the producer of the message.

1097

1098

1099

Demonstrating knowledge of a confirmation key associated with a token key-claim confirms the accompanying token claims. Knowledge of a confirmation key may be demonstrated using that key to create an XML Signature, for example. The relying party acceptance of the claims may depend on its confidence in the token. Multiple tokens may contain a key-claim for a signature and may be referenced from the signature using a `<wsse:SecurityTokenReference>`. A key-claim may be an X.509 Certificate token, or a Kerberos service ticket token to give two examples.

1100

1101

1102

1103

1104

1105

1106

1107

Because of the mutability of some SOAP headers, producers SHOULD NOT use the *Enveloped Signature Transform* defined in XML Signature. Instead, messages SHOULD explicitly include the elements to be signed. Similarly, producers SHOULD NOT use the *Enveloping Signature* defined in XML Signature [XMLSIG].

1108

1109

1110

1111

1112

This specification allows for multiple signatures and signature formats to be attached to a message, each referencing different, even overlapping, parts of the message. This is important for many distributed applications where messages flow through multiple processing stages. For example, a producer may submit an order that contains an orderID header. The producer signs the orderID header and the body of the request (the contents of the order). When this is received by the order processing sub-system, it may insert a shippingID into the header. The order sub-system would then sign, at a minimum, the orderID and the shippingID, and possibly the body as well. Then when this order is processed and shipped by the shipping department, a shippedInfo header might be appended. The shipping department would sign, at a minimum, the shippedInfo and the shippingID and possibly the body and forward the message to the billing department for processing. The billing department can verify the signatures and determine a valid chain of trust for the order, as well as who authorized each step in the process.

 1143
 1144
 1145

The Exclusive XML Canonicalization algorithm addresses the pitfalls of general canonicalization that can occur from *leaky* namespaces with pre-existing signatures.

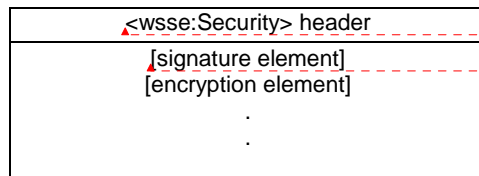

Finally, if a producer wishes to sign a message before encryption, then following the ordering rules laid out in section 5, "Security Header", they SHOULD first prepend the signature element to the `<wsse:Security>` header, and then prepend the encryption element, resulting in a `<wsse:Security>` header that has the encryption element first, followed by the signature element:

Formatted: Font: Helvetica
 Formatted Table
 Formatted: Font: Helvetica

1146
 1147
 1148
 1149
 1150
 1151

Likewise, if a producer wishes to sign a message after encryption, they SHOULD first prepend the encryption element to the `<wsse:Security>` header, and then prepend the signature element. This will result in a `<wsse:Security>` header that has the signature element first, followed by the encryption element:

 1167
 1168

The XML Digital Signature WG has defined two canonicalization algorithms: XML Canonicalization and Exclusive XML Canonicalization. To prevent confusion, the first is also called Inclusive Canonicalization. Neither one solves all possible problems that can arise. The following informal discussion is intended to provide guidance on the choice of which one to use in particular circumstances. For a more detailed and technically precise discussion of these issues see: [XML-C14N] and [EXC-C14N].

There are two problems to be avoided. On the one hand, XML allows documents to be changed in various ways and still be considered equivalent. For example, duplicate namespace declarations can be removed or created. As a result, XML tools make these kinds of changes freely when processing XML. Therefore, it is vital that these equivalent forms match the same signature.

On the other hand, if the signature simply covers something like `xx:foo`, its meaning may change if `xx` is redefined. In this case the signature does not prevent tampering. It might be thought that the problem could be solved by expanding all the values in line. Unfortunately, there are

Formatted: Font: 10 pt
 Deleted: . 15 March 2004
 Formatted: Font: 10 pt
 Deleted: 2004.

1169 mechanisms like XPATH which consider `xx="http://example.com/"`; to be different from
1170 `yy="http://example.com/"`; even though both `xx` and `yy` are bound to the same namespace.
1171 The fundamental difference between the Inclusive and Exclusive Canonicalization is the
1172 namespace declarations which are placed in the output. Inclusive Canonicalization copies all the
1173 declarations that are currently in force, even if they are defined outside of the scope of the
1174 signature. It also copies any `xml: attributes` that are in force, such as `xml: lang` or `xml: base`.
1175 This guarantees that all the declarations you might make use of will be unambiguously specified.
1176 The problem with this is that if the signed XML is moved into another XML document which has
1177 other declarations, the Inclusive Canonicalization will copy them and the signature will be invalid.
1178 This can even happen if you simply add an attribute in a different namespace to the surrounding
1179 context.

Deleted: ¶

1180
1181 Exclusive Canonicalization tries to figure out what namespaces you are actually using and just
1182 copies those. Specifically, it copies the ones that are "visibly used", which means the ones that
1183 are a part of the XML syntax. However, it does not look into attribute values or element content,
1184 so the namespace declarations required to process these are not copied. For example
1185 if you had an attribute like `xx:foo="yy:bar"` it would copy the declaration for `xx`, but not `yy`. (This
1186 can even happen without your knowledge because XML processing tools will add `xsi: type` if
1187 you use a schema subtype.) It also does not copy the `xml: attributes` that are declared outside the
1188 scope of the signature.

1189
1190 Exclusive Canonicalization allows you to create a list of the namespaces that must be declared,
1191 so that it will pick up the declarations for the ones that are not visibly used. The only problem is
1192 that the software doing the signing must know what they are. In a typical SOAP software
1193 environment, the security code will typically be unaware of all the namespaces being used by the
1194 application in the message body that it is signing.

Deleted: ¶

1195
1196 Exclusive Canonicalization is useful when you have a signed XML document that you wish to
1197 insert into other XML documents. A good example is a signed SAML assertion which might be
1198 inserted as a XML Token in the security header of various SOAP messages. The Issuer who
1199 signs the assertion will be aware of the namespaces being used and able to construct the list.
1200 The use of Exclusive Canonicalization will insure the signature verifies correctly every time.
1201 Inclusive Canonicalization is useful in the typical case of signing part or all of the SOAP body in
1202 accordance with this specification. This will insure all the declarations fall under the signature,
1203 even though the code is unaware of what namespaces are being used. At the same time, it is
1204 less likely that the signed data (and signature element) will be inserted in some other XML
1205 document. Even if this is desired, it still may not be feasible for other reasons, for example there
1206 may be `Id`'s with the same value defined in both XML documents.

1207
1208 In other situations it will be necessary to study the requirements of the application and the
1209 detailed operation of the canonicalization methods to determine which is appropriate.
1210 This section is non-normative.

1211 8.2 Signing Messages

1212 The `<wss:Security>` header block MAY be used to carry a signature compliant with the XML
1213 Signature specification within a SOAP Envelope for the purpose of signing one or more elements
1214 in the SOAP Envelope. Multiple signature entries MAY be added into a single SOAP Envelope
1215 within one `<wss:Security>` header block. Producers SHOULD sign all important elements of
1216 the message, and careful thought must be given to creating a signing policy that requires signing
1217 of parts of the message that might legitimately be altered in transit.

Formatted: Font: 10 pt

Deleted: 15 March 2004

- A compliant implementation MUST be capable of processing the required elements defined in the XML Signature specification.
- To add a signature to a `<wsse:Security>` header block, a `<ds:Signature>` element conforming to the XML Signature specification MUST be prepended to the existing content of the `<wsse:Security>` header block, in order to indicate to the receiver the correct order of operations. All the `<ds:Reference>` elements contained in the signature SHOULD refer to a resource within the enclosing SOAP envelope as described in the XML Signature specification. However, since the SOAP message exchange model allows intermediate applications to modify the Envelope (add or delete a header block; for example), XPath filtering does not always result in the same objects after message delivery. Care should be taken in using XPath filtering so that there is no subsequent validation failure due to such modifications.
- The problem of modification by intermediaries (especially active ones) is applicable to more than just XPath processing. Digital signatures, because of canonicalization and digests, present particularly fragile examples of such relationships. If overall message processing is to remain robust, intermediaries must exercise care that the transformation algorithms used do not affect the validity of a digitally signed component.
- Due to security concerns with namespaces, this specification strongly RECOMMENDS the use of the "Exclusive XML Canonicalization" algorithm or another canonicalization algorithm that provides equivalent or greater protection.
- For processing efficiency it is RECOMMENDED to have the signature added and then the security token pre-pended so that a processor can read and cache the token before it is used.

1268
1269

It is often desirable to sign security tokens that are included in a message or even external to the message. The XML Signature specification provides several common ways for referencing information to be signed such as URIs, IDs, and XPath, but some token formats may not allow tokens to be referenced using URIs or IDs and XPaths may be undesirable in some situations. This specification allows different tokens to have their own unique reference mechanisms which are specified in their profile as extensions to the `<wsse:SecurityTokenReference>` element. This element provides a uniform referencing mechanism that is guaranteed to work with all token formats. Consequently, this specification defines a new reference option for XML Signature: the STR Dereference Transform.

This transform is specified by the URI `#STR-Transform` (Note that URI fragments are relative to this document's URI) and when applied to a `<wsse:SecurityTokenReference>` element it means that the output is the token referenced by the `<wsse:SecurityTokenReference>` element not the element itself.

As an overview the processing model is to echo the input to the transform except when a `<wsse:SecurityTokenReference>` element is encountered. When one is found, the element is not echoed, but instead, it is used to locate the token(s) matching the criteria and rules defined by the `<wsse:SecurityTokenReference>` element and echo it (them) to the output. Consequently, the output of the transformation is the resultant sequence representing the input with any `<wsse:SecurityTokenReference>` elements replaced by the referenced security token(s) matched.

The following illustrates an example of this transformation which references a token contained within the message envelope:

The following describes the attributes and elements listed in the example above:

- /wsse:TransformationParameters*
This element is used to wrap parameters for a transformation allows elements even from the XML Signature namespace.
- /wsse:TransformationParameters/ds:Canonicalization*
This specifies the canonicalization algorithm to apply to the selected data.
- /wsse:TransformationParameters/{any}*
This is an extensibility mechanism to allow different (extensible) parameters to be specified in the future. Unrecognized parameters SHOULD cause a fault.
- /wsse:TransformationParameters/@{any}*
This is an extensibility mechanism to allow additional attributes, based on schemas, to be added to the element in the future. Unrecognized attributes SHOULD cause a fault.

The following is a detailed specification of the transformation. The algorithm is identified by the URI: #STR-Transform.

Deleted: ¶

Transform Input:

- The input is a node set. If the input is an octet stream, then it is automatically parsed; cf. XML Digital Signature [XMLSIG].

Transform Output:

- The output is an octet steam.

Syntax:

- The transform takes a single mandatory parameter, a <ds:CanonicalizationMethod> element, which is used to serialize the input node

set. Note, however, that the output may not be strictly in canonical form, per the canonicalization algorithm; however, the output is canonical, in the sense that it is unambiguous. However, because of syntax requirements in the XML Signature definition, this parameter MUST be wrapped in a `<wsse:TransformationParameters>` element.

•
Processing Rules:

- Let N be the input node set.
- Let R be the set of all `<wsse:SecurityTokenReference>` elements in N.
- For each R_i in R, let D_i be the result of dereferencing R_i .
- If D_i cannot be determined, then the transform MUST signal a failure.
- If D_i is an XML security token (e.g., a SAML assertion or a `<wsse:BinarySecurityToken>` element), then let R_i' be D_i . Otherwise, D_i is a raw binary security token; i.e., an octet stream. In this case, let R_i' be a node set consisting of a `<wsse:BinarySecurityToken>` element, utilizing the same namespace prefix as the `<wsse:SecurityTokenReference>` element R_i , with no `EncodingType` attribute, a `ValueType` attribute identifying the content of the security token, and text content consisting of the binary-encoded security token, with no white space.
- Finally, employ the canonicalization method specified as a parameter to the transform to serialize N to produce the octet stream output of this transform; but, in place of any dereferenced `<wsse:SecurityTokenReference>` element R_i and its descendants, process the dereferenced node set R_i' instead. During this step, canonicalization of the replacement node set MUST be augmented as follows:
 - o Note: A namespace declaration `xmlns=""` MUST be emitted with every apex element that has no namespace node declaring a value for the default namespace; cf. XML Decryption Transform.

Signing a SecurityTokenReference (STR) provides authentication and integrity protection of only the STR and not the referenced security token (ST). If signing the ST is the intended behavior, the STR Dereference Transform (STRDT) may be used which replaces the STR with the ST for digest computation, effectively protecting the ST and not the STR. If protecting both the ST and the STR is desired, you may sign the STR twice, once using the STRDT and once not using the STRDT.

The following table lists the full URI for each URI fragment referred to in the specification.

8.4 Signature Validation

The validation of a `<ds:Signature>` element inside an `<wsse:Security>` header block SHALL fail if:

- the syntax of the content of the element does not conform to this specification, or
- the validation of the signature contained in the element fails according to the core validation of the XML Signature specification [XMLESIG], or

- the application applying its own validation policy rejects the message for some reason (e.g., the signature is created by an untrusted key – verifying the previous two steps only performs cryptographic validation of the signature).

If the validation of the signature element fails, applications MAY report the failure to the producer using the fault codes defined in Section 12 Error Handling.

Formatted: Indent: Left: 0.25", No bullets or numbering

The signature validation shall additionally adhere to the rules defines in signature confirmation section below, if the initiator desires signature confirmation:

8.5 Signature Confirmation

In the general model, the initiator uses XML Signature constructs to represent message parts of the request that were signed. The manifest of signed SOAP elements is contained in the <ds:Signature> element which in turn is placed inside the <wsse:Security> header. The <ds:Signature> element of the request contains a <ds:SignatureValue>. This element contains a base64 encoded value representing the actual digital signature. In certain situations it is desirable that initiator confirms that the message received was generated in response to a message it initiated in its unaltered form. This helps prevent certain forms of attack. This specification introduces a <wsse11:SignatureConfirmation> element to address this necessity.

Compliant responder implementations that support signature confirmation, MUST include a <wsse11:SignatureConfirmation> element inside the <wsse:Security> header of the associated response message for every <ds:Signature> element that is a direct child of the <wsse:Security> header block in the originating message. The responder MUST include the contents of the <ds:SignatureValue> element of the request signature as the value of the @Value attribute of the <wsse11:SignatureConfirmation> element. The <wsse11:SignatureConfirmation> element MUST be included in the message signature of the associated response message.

If the associated originating signature is received in encrypted form then the corresponding <wsse11:SignatureConfirmation> element SHOULD be encrypted to protect the original signature and keys.

The schema outline for this element is as follows:

```
<SignatureConfirmation wsu:Id="..." Value="..." />
```

/SignatureConfirmation

This element indicates that the responder has processed the signature in the request. When this element is not present in a response the initiator SHOULD interpret that the responder is not compliant with this functionality.

/SignatureConfirmation/@wsu:Id

Identifier to be used when referencing this element in the SignedInfo reference list of the signature of the associated response message. This attribute MUST be present so that un-ambiguous references can be made to this <wsse11:SignatureConfirmation> element.

/SignatureConfirmation/@Value

This optional attribute contains the contents of a <ds:SignatureValue> copied from the associated request. If the request was not signed, then this attribute MUST NOT be present. If this attribute is specified with an empty value, the initiator SHOULD interpret

Formatted: Font: 10 pt

Deleted: 15 March 2004

Formatted: Font: 10 pt

Deleted: 2004.

1418 this as incorrect behavior and process accordingly. When this attribute is not present, the
1419 initiator SHOULD interpret this to mean that the response is based on a request that was
1420 not signed.

1421 **8.5.1 Response Generation Rules**

1422 If the responder does not comply with this specification, it MUST NOT include any
1423 <wssell:SignatureConfirmation> elements in response messages it generates. If the
1424 responder complies with this specification, it MUST include at least one
1425 <wssell:SignatureConfirmation> element in the <wsse:Security> header in any
1426 response(s) associated with requests. That is, the normal messaging patterns are not altered.
1427 For every response message generated, the responder MUST include a
1428 <wssell:SignatureConfirmation> element for every <ds:Signature> element it
1429 processed from the original request message. The Value attribute MUST be set to the exact
1430 value of the <ds:SignatureValue> element of the corresponding <ds:Signature> element.
1431 If no <ds:Signature> elements are present in the original request message, the responder
1432 MUST include exactly one <wssell:SignatureConfirmation> element. The Value attribute
1433 of the <wssell:SignatureConfirmation> element MUST NOT be present. The responder
1434 MUST include all <wssell:SignatureConfirmation> elements in the message signature of
1435 the response message(s). If the <ds:Signature> element corresponding to a
1436 <wssell:SignatureConfirmation> element was encrypted in the original request message,
1437 the <wssell:SignatureConfirmation> element SHOULD be encrypted for the recipient of
1438 the response message(s).
1439

1440 **8.5.2 Response Processing Rules**

1441 The signature validation shall additionally adhere to the following processing guidelines, if the
1442 initiator desires signature confirmation:

- 1443 • If a response message does not contain a <wssell:SignatureConfirmation>
1444 element inside the <wsse:Security> header, the initiator SHOULD reject the response
1445 message.
- 1446 • If a response message does contain a <wssell:SignatureConfirmation> element
1447 inside the <wsse:Security> header but @Value attribute is not present on
1448 <wssell:SignatureConfirmation> element, and the associated request message
1449 did include a <ds:Signature> element, the initiator SHOULD reject the response
1450 message.
- 1451 • If a response message does contain a <wssell:SignatureConfirmation> element
1452 inside the <wsse:Security> header and the @Value attribute is present on the
1453 <wssell:SignatureConfirmation> element, but the associated request did not
1454 include a <ds:Signature> element, the initiator SHOULD reject the response
1455 message.
- 1456 • If a response message does contain a <wssell:SignatureConfirmation> element
1457 inside the <wsse:Security> header, and the associated request message did include
1458 a <ds:Signature> element and the @Value attribute is present but does not match the
1459 stored signature value of the associated request message, the initiator SHOULD reject
1460 the response message.
- 1461 • If a response message does not contain a <wssell:SignatureConfirmation>
1462 element inside the <wsse:Security> header corresponding to each
1463 <ds:Signature> element or if the @Value attribute present does not match the stored

9 Encryption

1514

1515 This specification allows encryption of any combination of body blocks, header blocks, and any of
1516 these sub-structures by either a common symmetric key shared by the producer and the recipient
1517 or a symmetric key carried in the message in an encrypted form.

1518

1519 In order to allow this flexibility, this specification leverages the XML Encryption standard. ~~This~~
1520 specification describes how ~~the two~~ elements ~~<xenc:ReferenceList> and~~
1521 ~~<xenc:EncryptedKey>~~ listed below and defined in XML Encryption can be used within the
1522 ~~<wsse:Security>~~ header block. When a producer or an active intermediary encrypts
1523 portion(s) of a SOAP message using XML Encryption, ~~it~~ MUST prepend a sub-element to the
1524 ~~<wsse:Security>~~ header block. Furthermore, the encrypting party MUST either prepend the
1525 sub-element to an existing ~~<wsse:Security>~~ header block for the intended recipients or create
1526 a new ~~<wsse:Security>~~ header block and insert the sub-element. The combined process of
1527 encrypting portion(s) of a message and adding one of these sub-elements is called an encryption
1528 step hereafter. The sub-element MUST contain the information necessary for the recipient to
1529 identify the portions of the message that it is able to decrypt.

1530

1531 ~~This specification additionally defines an element <wsse11:EncryptedHeader> for containing~~
1532 ~~encrypted SOAP header blocks. This specification RECOMMENDS an additional mechanism that~~
1533 ~~uses this element for encrypting SOAP header blocks that complies with SOAP processing~~
1534 ~~guidelines while preserving the confidentiality of attributes on the SOAP header blocks.~~

1535

All compliant implementations MUST be able to support the XML Encryption standard [XMLENC].

1536

9.1 xenc:ReferenceList

1537

1538 The ~~<xenc:ReferenceList>~~ element from XML Encryption [XMLENC] MAY be used to
1539 create a manifest of encrypted portion(s), which are expressed as ~~<xenc:EncryptedData>~~
1540 elements within the envelope. An element or element content to be encrypted by this encryption
1541 step MUST be replaced by a corresponding ~~<xenc:EncryptedData>~~ according to XML
1542 Encryption. All the ~~<xenc:EncryptedData>~~ elements created by this encryption step
1543 SHOULD be listed in ~~<xenc:DataReference>~~ elements inside one or more
1544 ~~<xenc:ReferenceList>~~ element.

1545

1546 Although in XML Encryption [XMLENC], ~~<xenc:ReferenceList>~~ was originally designed to
1547 be used within an ~~<xenc:EncryptedKey>~~ element (which implies that all the referenced
1548 ~~<xenc:EncryptedData>~~ elements are encrypted by the same key), this specification allows
1549 that ~~<xenc:EncryptedData>~~ elements referenced by the same ~~<xenc:ReferenceList>~~
1550 MAY be encrypted by different keys. Each encryption key can be specified in ~~<ds:KeyInfo>~~
1551 within individual ~~<xenc:EncryptedData>~~.

1551

1552 A typical situation where the ~~<xenc:ReferenceList>~~ sub-element is useful is that the
1553 producer and the recipient use a shared secret key. The following illustrates the use of this sub-
1554 element:

1555

1556

1557

1558

1559

1581
1582
1583
1584
1585
1586

When the encryption step involves encrypting elements or element contents within a SOAP envelope with a symmetric key, which is in turn to be encrypted by the recipient's key and embedded in the message, `<xenc:EncryptedKey>` MAY be used for carrying such an encrypted key. This sub-element SHOULD have a manifest, that is, an `<xenc:ReferenceList>` element, in order for the recipient to know the portions to be decrypted with this key. An element or element content to be encrypted by this encryption step MUST be replaced by a corresponding `<xenc:EncryptedData>` according to XML Encryption. All the `<xenc:EncryptedData>` elements created by this encryption step SHOULD be listed in the `<xenc:ReferenceList>` element inside this sub-element.

1587
1588

This construct is useful when encryption is done by a randomly generated symmetric key that is in turn encrypted by the recipient's public key. The following illustrates the use of this element:

1620
1621
1622

While XML Encryption specifies that `<xenc:EncryptedKey>` elements MAY be specified in `<xenc:EncryptedData>` elements, this specification strongly RECOMMENDS that `<xenc:EncryptedKey>` elements be placed in the `<wsse:Security>` header.

1623

9.3 Encrypted Header

1624
1625
1626
1627
1628

In order to be compliant with SOAP mustUnderstand processing guidelines and to prevent disclosure of information contained in attributes on a SOAP header block, this specification introduces an `<wsse11:EncryptedHeader>` element. This element contains exactly one `<xenc:EncryptedData>` element. This specification RECOMMENDS the use of `<wsse11:EncryptedHeader>` element for encrypting SOAP header blocks.

1629

9.4 Processing Rules

1630
1631
1632
1633
1634
1635
1636
1637

Encrypted parts or using one of the sub-elements defined above MUST be in compliance with the XML Encryption specification. An encrypted SOAP envelope MUST still be a valid SOAP envelope. The message creator MUST NOT encrypt the `<S11:Envelope>`, `<S12:Envelope>`, `<S11:Body>`, `<S12:Body>` elements but MAY encrypt child elements of either the `<S11:Header>`, `<S12:Header>` and `<S11:Body>` or `<S12:Body>` elements. Multiple steps of encryption MAY be added into a single `<wsse:Security>` header block if they are targeted for the same recipient.

Deleted: , <S11:Header>, <S12:Header> ,

1638
1639
1640
1641
1642
1643
1644

When an element or element content inside a SOAP envelope (e.g. the contents of the `<S11:Body>` or `<S12:Body>` elements) are to be encrypted, it MUST be replaced by an `<xenc:EncryptedData>`, according to XML Encryption and it SHOULD be referenced from the `<xenc:ReferenceList>` element created by this encryption step. If the target of reference is an `EncryptedHeader` as defined in section 9.3 above, see processing rules defined in section 9.5.3 Encryption using `EncryptedHeader` and section 9.5.4 Decryption of `EncryptedHeader` below.

1645

9.4.1 Encryption

1646
1647
1648
1649
1650
1651
1652
1653
1654
1655
1656
1657
1658

The general steps (non-normative) for creating an encrypted SOAP message in compliance with this specification are listed below (note that use of `<xenc:ReferenceList>` is RECOMMENDED. Additionally, if target of encryption is a SOAP header, processing rules defined in section 9.5.3 SHOULD be used.

Deleted:).

- Create a new SOAP envelope.
- Create a `<wsse:Security>` header
- When an `<xenc:EncryptedKey>` is used, create a `<xenc:EncryptedKey>` sub-element of the `<wsse:Security>` element. This `<xenc:EncryptedKey>` sub-element SHOULD contain an `<xenc:ReferenceList>` sub-element, containing a `<xenc:DataReference>` to each `<xenc:EncryptedData>` element that was encrypted using that key.
- Locate data items to be encrypted, i.e., XML elements, element contents within the target SOAP envelope.

Formatted: Bulleted + Level: 1 + Aligned at: 0.25" + Tab after: 0.5" + Indent at: 0.5"

Formatted: Font: 10 pt

Deleted: . 15 March 2004

Formatted: Font: 10 pt

Deleted: 2004.

- 1659 • Encrypt the data items as follows: For each XML element or element content within the
1660 target SOAP envelope, encrypt it according to the processing rules of the XML
1661 Encryption specification [XMLENC]. Each selected original element or element content
1662 MUST be removed and replaced by the resulting `<xenc:EncryptedData>` element.
- 1663 • The optional `<ds:KeyInfo>` element in the `<xenc:EncryptedData>` element MAY
1664 reference another `<ds:KeyInfo>` element. Note that if the encryption is based on an
1665 attached security token, then a `<wsse:SecurityTokenReference>` element SHOULD
1666 be added to the `<ds:KeyInfo>` element to facilitate locating it.
- 1667 • Create an `<xenc:DataReference>` element referencing the generated
1668 `<xenc:EncryptedData>` elements. Add the created `<xenc:DataReference>`
1669 element to the `<xenc:ReferenceList>`.
- 1670 • Copy all non-encrypted data.

Formatted: Font: Courier New

1671 9.4.2 Decryption

1672 On receiving a SOAP envelope containing encryption header elements, for each encryption
1673 header element the following general steps should be processed (this section is non-normative.
1674 Additionally, if the target of reference is an EncryptedHeader, processing rules as defined in
1675 section 9.5.4 below SHOULD be used):

- 1677 1. Identify any decryption keys that are in the recipient's possession, then identifying any
1678 message elements that it is able to decrypt.
- 1679 2. Locate the `<xenc:EncryptedData>` items to be decrypted (possibly using the
1680 `<xenc:ReferenceList>`).
- 1681 3. Decrypt them as follows:
 - 1682 a. For each element in the target SOAP envelope, decrypt it according to the
1683 processing rules of the XML Encryption specification and the processing rules
1684 listed above.
 - 1685 b. If the decryption fails for some reason, applications MAY report the failure to the
1686 producer using the fault code defined in Section 12 Error Handling of this
1687 specification.
 - 1688 c. It is possible for overlapping portions of the SOAP message to be encrypted in
1689 such a way that they are intended to be decrypted by SOAP nodes acting in
1690 different Roles. In this case, the `<xenc:ReferenceList>` or
1691 `<xenc:EncryptedKey>` elements identifying these encryption operations will
1692 necessarily appear in different `<wsse:Security>` headers. Since SOAP does
1693 not provide any means of specifying the order in which different Roles will
1694 process their respective headers, this order is not specified by this specification
1695 and can only be determined by a prior agreement.

Deleted: <#>Decryption Transformation¶
The ordering semantics of the `<wsse:Security>` header are sufficient to determine if signatures are over encrypted or unencrypted data. However, when a signature is included in one `<wsse:Security>` header and the encryption data is in another `<wsse:Security>` header, the proper processing order may not be apparent.¶
If the producer wishes to sign a message that MAY subsequently be encrypted by an intermediary then the producer MAY use the Decryption Transform for XML Signature to explicitly specify the order of decryption.¶

1696 9.4.3 Encryption with EncryptedHeader

1697 When it is required that an entire SOAP header block including the top-level element and its
1698 attributes be encrypted, the original header block SHOULD be replaced with a
1699 `<wsse11:EncryptedHeader>` element. The `<wsse11:EncryptedHeader>` element MUST
1700 contain the `<xenc:EncryptedData>` produced by encrypting the header block. A `wsu:Id`
1701 attribute MAY be added to the `<wsse11:EncryptedHeader>` element for referencing. If the
1702 referencing `<wsse:Security>` header block defines a value for the `<S12:mustUnderstand>`
1703 or `<S11:mustUnderstand>` attribute, that attribute and associated value MUST be copied to
1704 the `<wsse11:EncryptedHeader>` element. If the referencing `<wsse:Security>` header

Formatted: Bullets and Numbering

Formatted: Font: 10 pt

Deleted: 15 March 2004

Formatted: Font: 10 pt

Deleted: 2004.

1705 block defines a value for the S12:Role or S11:Actor attribute, that attribute and associated value
1706 MUST be copied to the <wssell:EncryptedHeader> element.
1707
1708 Any header block can be replaced with a corresponding <wssell:EncryptedHeader> header
1709 block. This includes <wsse:Security> header blocks. (In this case, obviously if the encryption
1710 operation is specified in the same security header or in a security header targeted at a node
1711 which is reached after the node targeted by the <wssell:EncryptedHeader> element, the
1712 decryption will not occur.)
1713 In addition, <wssell:EncryptedHeader> header blocks can be super-encrypted and replaced
1714 by other <wssell:EncryptedHeader> header blocks (for wrapping/tunneling scenarios). Any
1715 <wsse:Security> header that encrypts a header block targeted to a particular actor SHOULD
1716 be targeted to that same actor, unless it is a security header.

1717 **9.4.4 Processing an EncryptedHeader**

1718 The processing model for <wssell:EncryptedHeader> header blocks is as follows:

- 1719 1. Resolve references to encrypted data specified in the <wsse:Security> header block
1720 targeted at this node. For each reference, perform the following steps.
- 1721 2. If the referenced element does not have a qualified name of
1722 <wssell:EncryptedHeader> then process as per section 9.5.2 Decryption and stop
1723 the processing steps here.
- 1724 3. Otherwise, extract the <xenc:EncryptedData> element from the
1725 <wssell:EncryptedHeader> element.
- 1726 4. Decrypt the contents of the <xenc:EncryptedData> element as per section 9.5.2
1727 Decryption and replace the <wssell:EncryptedHeader> element with the decrypted
1728 contents.
- 1729 5. Process the decrypted header block as per SOAP processing guidelines.

1731 Alternatively, a processor may perform a pre-pass over the encryption references in the
1732 <wsse:Security> header:

- 1733 1. Resolve references to encrypted data specified in the <wsse:Security> header block
1734 targeted at this node. For each reference, perform the following steps.
- 1735 2. If a referenced element has a qualified name of <wssell:EncryptedHeader> then
1736 replace the <wssell:EncryptedHeader> element with the contained
1737 <xenc:EncryptedData> element and if present copy the value of the wsu:Id attribute
1738 from the <wssell:EncryptedHeader> element to the <xenc:EncryptedData>
1739 element.
- 1740 3. Process the <wsse:Security> header block as normal.

1742 It should be noted that the results of decrypting a <wssell:EncryptedHeader> header block
1743 could be another <wssell:EncryptedHeader> header block. In addition, the result MAY be
1744 targeted at a different role than the role processing the <wssell:EncryptedHeader> header
1745 block.

9.4.5 Processing the mustUnderstand attribute on EncryptedHeader

If the S11:mustUnderstand or S12:mustUnderstand attribute is specified on the <wssell:EncryptedHeader> header block, and is true, then the following steps define what it means to "understand" the <wssell:EncryptedHeader> header block:

1. The processor MUST be aware of this element and know how to decrypt and convert into the original header block. This DOES NOT REQUIRE that the process know that it has the correct keys or support the indicated algorithms.
2. The processor MUST, after decrypting the encrypted header block, process the decrypted header block according to the SOAP processing guidelines. The receiver MUST raise a fault if any content required to adequately process the header block remains encrypted or if the decrypted SOAP header is not understood and the value of the S12:mustUnderstand or S11:mustUnderstand attribute on the decrypted header block is true. Note that in order to comply with SOAP processing rules in this case, the processor must roll back any persistent effects of processing the security header, such as storing a received token.

10 Security Timestamps

1762

1763 It is often important for the recipient to be able to determine the *freshness* of security semantics.
1764 In some cases, security semantics may be so *stale* that the recipient may decide to ignore it.
1765 This specification does not provide a mechanism for synchronizing time. The assumption is that
1766 time is trusted or additional mechanisms, not described here, are employed to prevent replay.
1767 This specification defines and illustrates time references in terms of the `xsd:dateTime` type
1768 defined in XML Schema. It is RECOMMENDED that all time references use this type. It is further
1769 RECOMMENDED that all references be in UTC time. Implementations MUST NOT generate time
1770 instants that specify leap seconds. If, however, other time types are used, then the `ValueType`
1771 attribute (described below) MUST be specified to indicate the data type of the time format.
1772 Requestors and receivers SHOULD NOT rely on other applications supporting time resolution
1773 finer than milliseconds.

1774

1775 The `<wsu:Timestamp>` element provides a mechanism for expressing the creation and
1776 expiration times of the security semantics in a message.

1777

1778 All times MUST be in UTC format as specified by the XML Schema type (`dateTime`). It should be
1779 noted that times support time precision as defined in the XML Schema specification.

1780 The `<wsu:Timestamp>` element is specified as a child of the `<wsse:Security>` header and
1781 may only be present at most once per header (that is, per SOAP actor/role).

1782

1783 The ordering within the element is as illustrated below. The ordering of elements in the
1784 `<wsu:Timestamp>` element is fixed and MUST be preserved by intermediaries.

1785 The schema outline for the `<wsu:Timestamp>` element is as follows:

1786

```
1787 <wsu:Timestamp wsu:Id="...">  
1788   <wsu:Created ValueType="...">...</wsu:Created>  
1789   <wsu:Expires ValueType="...">...</wsu:Expires>  
1790   ...  
1791 </wsu:Timestamp>
```

1792

1793 The following describes the attributes and elements listed in the schema above:

1794

1795 `/wsu:Timestamp`

1796 This is the element for indicating message timestamps.

1797

1798 `/wsu:Timestamp/wsui:Created`

1799 This represents the creation time of the security semantics. This element is optional, but
1800 can only be specified once in a `<wsu:Timestamp>` element. Within the SOAP
1801 processing model, creation is the instant that the infonet is serialized for transmission.
1802 The creation time of the message SHOULD NOT differ substantially from its transmission
1803 time. The difference in time should be minimized.

1804

1805 `/wsu:Timestamp/wsui:Expires`

1806 This element represents the expiration of the security semantics. This is optional, but
1807 can appear at most once in a `<wsu:Timestamp>` element. Upon expiration, the
1808 requestor asserts that its security semantics are no longer valid. It is strongly
1809 RECOMMENDED that recipients (anyone who processes this message) discard (ignore)

Deleted: 2004.

1810 any message whose security semantics have passed their expiration. A Fault code
1811 (`wsu:MessageExpired`) is provided if the recipient wants to inform the requestor that its
1812 security semantics were expired. A service MAY issue a Fault indicating the security
1813 semantics have expired.

1814 |
1815 `/wsu:Timestamp/{any}`
1816 This is an extensibility mechanism to allow additional elements to be added to the
1817 element. Unrecognized elements SHOULD cause a fault.

1818 |
1819 `/wsu:Timestamp/@wsu:Id`
1820 This optional attribute specifies an XML Schema ID that can be used to reference this
1821 element (the timestamp). This is used, for example, to reference the timestamp in a XML
1822 Signature.

1823 |
1824 `/wsu:Timestamp/@{any}`
1825 This is an extensibility mechanism to allow additional attributes to be added to the
1826 element. Unrecognized attributes SHOULD cause a fault.

1827 |
1828 The expiration is relative to the requestor's clock. In order to evaluate the expiration time,
1829 recipients need to recognize that the requestor's clock may not be synchronized to the recipient's
1830 clock. The recipient, therefore, MUST make an assessment of the level of trust to be placed in
1831 the requestor's clock, since the recipient is called upon to evaluate whether the expiration time is
1832 in the past relative to the requestor's, not the recipient's, clock. The recipient may make a
1833 judgment of the requestor's likely current clock time by means not described in this specification,
1834 for example an out-of-band clock synchronization protocol. The recipient may also use the
1835 creation time and the delays introduced by intermediate SOAP roles to estimate the degree of
1836 clock skew.

1837 |
1838 The following example illustrates the use of the `<wsu:Timestamp>` element and its content.

```
1839  
1840 <S11:Envelope xmlns:S11="..." xmlns:wssse="..." xmlns:wsu="...">  
1841   <S11:Header>  
1842     <wsse:Security>  
1843       <wsu:Timestamp wsu:Id="timestamp">  
1844         <wsu:Created>2001-09-13T08:42:00Z</wsu:Created>  
1845         <wsu:Expires>2001-10-13T09:00:00Z</wsu:Expires>  
1846       </wsu:Timestamp>  
1847       ...  
1848     </wsse:Security>  
1849     ...  
1850   </S11:Header>  
1851   <S11:Body>  
1852     ...  
1853   </S11:Body>  
1854 </S11:Envelope>

1855

11 Extended Example

1856

The following sample message illustrates the use of security tokens, signatures, and encryption.

1857

For this example, the timestamp and the message body are signed prior to encryption. The

1858

decryption transformation is not needed as the signing/encryption order is specified within the

1859

<wsse:Security> header.

```

1948 Let's review some of the key sections of this example:
1949 Lines (003)-(058) contain the SOAP message headers.

1951 Lines (004)-(057) represent the <wsse:Security> header block. This contains the security-
1952 related information for the message.

1954 Lines (005)-(008) specify the timestamp information. In this case it indicates the creation time of
1955 the security semantics.

1957 Lines (010)-(012) specify a security token that is associated with the message. In this case, it
1958 specifies an X.509 certificate that is encoded as Base64. Line (011) specifies the actual Base64
1959 encoding of the certificate.

1961 Lines (013)-(026) specify the key that is used to encrypt the body of the message. Since this is a
1962 symmetric key, it is passed in an encrypted form. Line (014) defines the algorithm used to
1963 encrypt the key. Lines (015)-(018) specify the identifier of the key that was used to encrypt the
1964 symmetric key. Lines (019)-(022) specify the actual encrypted form of the symmetric key. Lines

Formatted: Font: 10 pt

Deleted: 15 March 2004

Formatted: Font: 10 pt

Deleted: 2004.

1965 (023)-(025) identify the encryption block in the message that uses this symmetric key. In this
1966 case it is only used to encrypt the body (Id="enc1").
1967 |
1968 Lines (027)-(056) specify the digital signature. In this example, the signature is based on the
1969 X.509 certificate. Lines (028)-(047) indicate what is being signed. Specifically, line (039)
1970 references the message body.
1971 |
1972 Lines (048)-(050) indicate the actual signature value – specified in Line (043).
1973 |
1974 Lines (052)-(054) indicate the key that was used for the signature. In this case, it is the X.509
1975 certificate included in the message. Line (053) provides a URI link to the Lines (010)-(012).
1976 The body of the message is represented by Lines (059)-(067).
1977 |
1978 Lines (060)-(066) represent the encrypted metadata and form of the body using XML Encryption.
1979 Line (060) indicates that the "element value" is being replaced and identifies this encryption. Line
1980 (061) specifies the encryption algorithm – Triple-DES in this case. Lines (063)-(064) contain the
1981 actual cipher text (i.e., the result of the encryption). Note that we don't include a reference to the
1982 key as the key references this encryption – Line (024).

12 Error Handling

There are many circumstances where an *error* can occur while processing security information. For example:

- Invalid or unsupported type of security token, signing, or encryption
- Invalid or unauthenticated or unauthenticatable security token
- Invalid signature
- Decryption failure
- Referenced security token is unavailable
- Unsupported namespace

Formatted: Bulleted + Level: 1 + Aligned at: 0.25" + Tab after: 0.5" + Indent at: 0.5"

If a service does not perform its normal operation because of the contents of the Security header, then that MAY be reported using SOAP's Fault Mechanism. This specification does not mandate that faults be returned as this could be used as part of a denial of service or cryptographic attack. We combine signature and encryption failures to mitigate certain types of attacks.

If a failure is returned to a producer then the failure MUST be reported using the SOAP Fault mechanism. The following tables outline the predefined security fault codes. The "unsupported" classes of errors are as follows. Note that the reason text provided below is RECOMMENDED, but alternative text MAY be provided if more descriptive or preferred by the implementation. The tables below are defined in terms of SOAP 1.1. For SOAP 1.2, the Fault/Code/Value is *env:Sender* (as defined in SOAP 1.2) and the Fault/Code/Subcode/Value is the *faultcode* below and the Fault/Reason/Text is the *faultstring* below.

Error that occurred (faultstring)	Faultcode
An unsupported token was provided	wsse:UnsupportedSecurityToken
An unsupported signature or encryption algorithm was used	wsse:UnsupportedAlgorithm

Formatted Table

2007
2008
2009

The "failure" class of errors are:

Error that occurred (faultstring)	faultcode
An error was discovered processing the <wsse:Security> header.	wsse:InvalidSecurity
An invalid security token was provided	wsse:InvalidSecurityToken
The security token could not be authenticated or authorized	wsse:FailedAuthentication
The signature or decryption was invalid	wsse:FailedCheck
Referenced security token could not be retrieved	wsse:SecurityTokenUnavailable

13 Security Considerations

As stated in the Goals and Requirements section of this document, this specification is meant to provide extensible framework and flexible syntax, with which one could implement various security mechanisms. This framework and syntax by itself *does not provide any guarantee of security*. When implementing and using this framework and syntax, one must make every effort to ensure that the result is not vulnerable to any one of a wide range of attacks.

2018

13.1 General Considerations

2019
2020
2021
2022
2023

It is not feasible to provide a comprehensive list of security considerations for such an extensible set of mechanisms. A complete security analysis MUST be conducted on specific solutions based on this specification. Below we illustrate some of the security concerns that often come up with protocols of this type, but we stress that this *is not an exhaustive list of concerns*.

2024
2025
2026
2027
2028
2029
2030
2031
2032
2033
2034
2035
2036
2037
2038

- freshness guarantee (e.g., the danger of replay, delayed messages and the danger of relying on timestamps assuming secure clock synchronization)
- proper use of digital signature and encryption (signing/encrypting critical parts of the message, interactions between signatures and encryption), i.e., signatures on (content of) encrypted messages leak information when in plain-text)
- protection of security tokens (integrity)
- certificate verification (including revocation issues)
- the danger of using passwords without utmost protection (i.e. dictionary attacks against passwords, replay, insecurity of password derived keys, ...)
- the use of randomness (or strong pseudo-randomness)
- interaction between the security mechanisms implementing this standard and other system component
- man-in-the-middle attacks
- PKI attacks (i.e. identity mix-ups)

Formatted: Bulleted + Level: 1 + Aligned at: 0.25" + Tab after: 0.5" + Indent at: 0.5"

2039
2040
2041

There are other security concerns that one may need to consider in security protocols. The list above should not be used as a "check list" instead of a comprehensive security analysis. The next section will give a few details on some of the considerations in this list.

2042

13.2 Additional Considerations

Formatted: Bullets and Numbering

2043

13.2.1 Replay

2044
2045
2046
2047
2048
2049
2050
2051

Digital signatures alone do not provide message authentication. One can record a signed message and resend it (a replay attack). It is strongly RECOMMENDED that messages include digitally signed elements to allow message recipients to detect replays of the message when the messages are exchanged via an open network. These can be part of the message or of the headers defined from other SOAP extensions. Four typical approaches are: Timestamp, Sequence Number, Expirations and Message Correlation. Signed timestamps MAY be used to keep track of messages (possibly by caching the most recent timestamp from a specific service) and detect replays of previous messages. It is RECOMMENDED that timestamps be cached for

Page 52 of 69

2052 a given period of time, as a guideline, a value of five minutes can be used as a minimum to detect
2053 replays, and that timestamps older than that given period of time set be rejected in interactive
2054 scenarios.

2055 **13.2.2 Combining Security Mechanisms**

2056 This specification defines the use of XML Signature and XML Encryption in SOAP headers. As
2057 one of the building blocks for securing SOAP messages, it is intended to be used in conjunction
2058 with other security techniques. Digital signatures need to be understood in the context of other
2059 security mechanisms and possible threats to an entity.

2060 Implementers should also be aware of all the security implications resulting from the use of digital
2061 signatures in general and XML Signature in particular. When building trust into an application
2062 based on a digital signature there are other technologies, such as certificate evaluation, that must
2063 be incorporated, but these are outside the scope of this document.

2064 As described in XML Encryption, the combination of signing and encryption over a common data
2065 item may introduce some cryptographic vulnerability. For example, encrypting digitally signed
2066 data, while leaving the digital signature in the clear, may allow plain text guessing attacks.

2069 **13.2.3 Challenges**

2070 When digital signatures are used for verifying the claims pertaining to the sending entity, the
2071 producer must demonstrate knowledge of the confirmation key. One way to achieve this is to use
2072 a challenge-response type of protocol. Such a protocol is outside the scope of this document.
2073 To this end, the developers can attach timestamps, expirations, and sequences to messages.

2074 **13.2.4 Protecting Security Tokens and Keys**

2075 Implementers should be aware of the possibility of a token substitution attack. In any situation
2076 where a digital signature is verified by reference to a token provided in the message, which
2077 specifies the key, it may be possible for an unscrupulous producer to later claim that a different
2078 token, containing the same key, but different information was intended.

2079 An example of this would be a user who had multiple X.509 certificates issued relating to the
2080 same key pair but with different attributes, constraints or reliance limits. Note that the signature of
2081 the token by its issuing authority does not prevent this attack. Nor can an authority effectively
2082 prevent a different authority from issuing a token over the same key if the user can prove
2083 possession of the secret.

2084 The most straightforward counter to this attack is to insist that the token (or its unique identifying
2085 data) be included under the signature of the producer. If the nature of the application is such that
2086 the contents of the token are irrelevant, assuming it has been issued by a trusted authority, this
2087 attack may be ignored. However because application semantics may change over time, best
2088 practice is to prevent this attack.

2089 Requestors should use digital signatures to sign security tokens that do not include signatures (or
2090 other protection mechanisms) to ensure that they have not been altered in transit. It is strongly
2091 RECOMMENDED that all relevant and immutable message content be signed by the producer.
2092 Receivers SHOULD only consider those portions of the document that are covered by the
2093 producer's signature as being subject to the security tokens in the message. Security tokens
2094 appearing in `<wsse:Security>` header elements SHOULD be signed by their issuing authority
2095 so that message receivers can have confidence that the security tokens have not been forged or
2096 altered since their issuance. It is strongly RECOMMENDED that a message producer sign any
2097
2098

Formatted: Font: 10 pt

Deleted: 15 March 2004

Formatted: Font: 10 pt

Deleted: 2004.

2099 <wsse:SecurityToken> elements that it is confirming and that are not signed by their issuing
2100 authority.
2101 When a requester provides, within the request, a Public Key to be used to encrypt the response,
2102 it is possible that an attacker in the middle may substitute a different Public Key, thus allowing the
2103 attacker to read the response. The best way to prevent this attack is to bind the encryption key in
2104 some way to the request. One simple way of doing this is to use the same key pair to sign the
2105 request as to encrypt the response. However, if policy requires the use of distinct key pairs for
2106 signing and encryption, then the Public Key provided in the request should be included under the
2107 signature of the request.

2108 **13.2.5 Protecting Timestamps and Ids**

2109 In order to *trust* wsu:Id attributes and <wsu:Timestamp> elements, they SHOULD be signed
2110 using the mechanisms outlined in this specification. This allows readers of the IDs and
2111 timestamps information to be certain that the IDs and timestamps haven't been forged or altered
2112 in any way. It is strongly RECOMMENDED that IDs and timestamp elements be signed.
2113

2114 **13.2.6 Protecting against removal and modification of XML Elements**

2115 XML Signatures using Shorthand XPointer References (AKA IDREF) protect against the removal
2116 and modification of XML elements; but do not protect the location of the element within the XML
2117 Document.

2118
2119 Whether or not this is security vulnerability depends on whether the location of the signed data
2120 within its surrounding context has any semantic import. This consideration applies to data carried
2121 in the SOAP Body or the Header.

2122
2123 Of particular concern is the ability to relocate signed data into a SOAP Header block which is
2124 unknown to the receiver and marked mustUnderstand="false". This could have the effect of
2125 causing the receiver to ignore signed data which the sender expected would either be processed
2126 or result in the generation of a mustUnderstand fault.

2127
2128 A similar exploit would involve relocating signed data into a SOAP Header block targeted to a
2129 S11:actor or S12:role other than that which the sender intended, and which the receiver will not
2130 process.

2131
2132 While these attacks could apply to any portion of the message, their effects are most pernicious
2133 with SOAP header elements which may not always be present, but must be processed whenever
2134 they appear.

2135
2136 In the general case of XML Documents and Signatures, this issue may be resolved by signing the
2137 entire XML Document and/or strict XML Schema specification and enforcement. However,
2138 because elements of the SOAP message, particularly header elements, may be legitimately
2139 modified by SOAP intermediaries, this approach is usually not appropriate. It is RECOMMENDED
2140 that applications signing any part of the SOAP body sign the entire body.

2141
2142 Alternatives countermeasures include (but are not limited to):

- 2143 • References using XPath transforms with Absolute Path expressions.
- 2144 • A Reference using an XPath transform to include any significant location-dependent
2145 elements and exclude any elements that might legitimately be removed, added, or altered
2146 by intermediaries.
- 2147 • Using only References to elements with location-independent semantics.

Formatted: Font: 10 pt

Deleted: 15 March 2004

Deleted: 2004.

2148
2149
2150
2151
2152
2153
2154
2155
2156

- Strict policy specification and enforcement regarding which message parts are to be signed. For example:
 - Requiring that the entire SOAP Body and all children of SOAP Header be signed.
 - Requiring that SOAP header elements which are marked mustUnderstand="false" and have signed descendants MUST include the mustUnderstand attribute under the signature.

2157

14 Interoperability Notes

2158

Based on interoperability experiences with this and similar specifications, the following list highlights several common areas where interoperability issues have been discovered. Care should be taken when implementing to avoid these issues. It should be noted that some of these may seem "obvious", but have been problematic during testing.

2159

2160

2161

2162

2163

2164

2165

2166

2167

2168

2169

2170

2171

2172

2173

2174

2175

2176

2177

2178

2179

2180

2181

2182

2183

2184

This section is non-normative.

- **Key Identifiers:** Make sure you understand the algorithm and how it is applied to security tokens.
- **EncryptedKey:** The `<xenc:EncryptedKey>` element from XML Encryption requires a `Type` attribute whose value is one of a pre-defined list of values. Ensure that a correct value is used.
- **Encryption Padding:** The XML Encryption random block cipher padding has caused issues with certain decryption implementations; be careful to follow the specifications exactly.
- **IDs:** The specification recognizes three specific ID elements: the global `wsu:Id` attribute and the local `Id` attributes on XML Signature and XML Encryption elements (because the latter two do not allow global attributes). If any other element does not allow global attributes, it cannot be directly signed using an ID reference. Note that the global attribute `wsu:Id` MUST carry the namespace specification.
- **Time Formats:** This specification uses a restricted version of the XML Schema `xsd:dateTime` element. Take care to ensure compliance with the specified restrictions.
- **Byte Order Marker (BOM):** Some implementations have problems processing the BOM marker. It is suggested that usage of this be optional.
- **SOAP, WSDL, HTTP:** Various interoperability issues have been seen with incorrect SOAP, WSDL, and HTTP semantics being applied. Care should be taken to carefully adhere to these specifications and any interoperability guidelines that are available.

2185

15 Privacy Considerations

2186

In the context of this specification, we are only concerned with potential privacy violation by the security elements defined here. Privacy of the content of the payload message is out of scope.

2187

2188

Producers or sending applications should be aware that claims, as collected in security tokens, are typically personal information, and should thus only be sent according to the producer's

2189

2190

privacy policies. Future standards may allow privacy obligations or restrictions to be added to this data. Unless such standards are used, the producer must ensure by out-of-band means that the recipient is bound to adhering to all restrictions associated with the data, and the recipient must similarly ensure by out-of-band means that it has the necessary consent for its intended processing of the data.

2191

2192

2193

2194

2195

2196

If claim data are visible to intermediaries, then the policies must also allow the release to these intermediaries. As most personal information cannot be released to arbitrary parties, this will typically require that the actors are referenced in an identifiable way; such identifiable references are also typically needed to obtain appropriate encryption keys for the intermediaries.

2197

2198

2199

2200

If intermediaries add claims, they should be guided by their privacy policies just like the original producers.

2201

2202

2203

Intermediaries may also gain traffic information from a SOAP message exchange, e.g., who communicates with whom at what time. Producers that use intermediaries should verify that releasing this traffic information to the chosen intermediaries conforms to their privacy policies.

Appendix C: Utility Elements and Attributes

2270
2271
2272
2273
2274

These specifications define several elements, attributes, and attribute groups which can be re-used by other specifications. This appendix provides an overview of these *utility* components. It should be noted that the detailed descriptions are provided in the specification and this appendix will reference these sections as well as calling out other aspects not documented in the specification.

Formatted: No bullets or numbering

2275

16.1 Identification Attribute

2276
2277
2278
2279
2280
2281
2282

There are many situations where elements within SOAP messages need to be referenced. For example, when signing a SOAP message, selected elements are included in the signature. XML Schema Part 2 provides several built-in data types that may be used for identifying and referencing elements, but their use requires that consumers of the SOAP message either have or are able to obtain the schemas where the identity or reference mechanisms are defined. In some circumstances, for example, intermediaries, this can be problematic and not desirable.

2283
2284
2285
2286
2287

Consequently a mechanism is required for identifying and referencing elements, based on the SOAP foundation, which does not rely upon complete schema knowledge of the context in which an element is used. This functionality can be integrated into SOAP processors so that elements can be identified and referred to without dynamic schema discovery and processing.

2288
2289
2290
2291
2292

This specification specifies a namespace-qualified global attribute for identifying an element which can be applied to any element that either allows arbitrary attributes or specifically allows this attribute. This is a general purpose mechanism which can be re-used as needed. A detailed description can be found in Section 4.0 ID References.

2293

This section is non-normative.

Formatted: No bullets or numbering

2294

16.2 Timestamp Elements

2295
2296
2297
2298

The specification defines XML elements which may be used to express timestamp information such as creation and expiration. While defined in the context of message security, these elements can be re-used wherever these sorts of time statements need to be made.

2299
2300
2301
2302
2303
2304
2305

The elements in this specification are defined and illustrated using time references in terms of the *dateTime* type defined in XML Schema. It is RECOMMENDED that all time references use this type for interoperability. It is further RECOMMENDED that all references be in UTC time for increased interoperability. If, however, other time types are used, then the `valueType` attribute MUST be specified to indicate the data type of the time format. The following table provides an overview of these elements:

Element	Description
<wsu:Created>	This element is used to indicate the creation time associated with the enclosing context.
<wsu:Expires>	This element is used to indicate the expiration time associated with the enclosing context.

Formatted Table

2306
2307
2308

A detailed description can be found in Section 10.

Deleted: 2004.

2309 This section is non-normative.
2310

2311 **16.3 General Schema Types**

2312 The schema for the utility aspects of this specification also defines some general purpose
2313 schema elements. While these elements are defined in this schema for use with this
2314 specification, they are general purpose definitions that may be used by other specifications as
2315 well.

2316 Specifically, the following schema elements are defined and can be re-used:
2317
2318

Schema Element	Description
wsu:commonAtts attribute group	This attribute group defines the common attributes recommended for elements. This includes the <code>wsu:Id</code> attribute as well as extensibility for other namespace qualified attributes.
wsu:AttributedDateTime type	This type extends the XML Schema <code>dateTime</code> type to include the common attributes.
wsu:AttributedURI type	This type extends the XML Schema <code>anyURI</code> type to include the common attributes.

2319 This section is non-normative.

2322

Appendix D: SecurityTokenReference Model

2323

This appendix provides a non-normative overview of the usage and processing models for the <wsse:SecurityTokenReference> element.

2324

2325

2326

There are several motivations for introducing the <wsse:SecurityTokenReference> element:

2327

2328

- The XML Signature reference mechanisms are focused on "key" references rather than general token references.

Formatted: Bulleted + Level: 1 + Aligned at: 0.25" + Tab after: 0.5" + Indent at: 0.5"

2329

2330

- The XML Signature reference mechanisms utilize a fairly closed schema which limits the extensibility that can be applied.

2331

2332

- There are additional types of general reference mechanisms that are needed, but are not covered by XML Signature.

2333

2334

- There are scenarios where a reference may occur outside of an XML Signature and the XML Signature schema is not appropriate or desired.

2335

2336

- The XML Signature references may include aspects (e.g. transforms) that may not apply to all references.

2337

2338

The following use cases drive the above motivations:

2339

2340

Local Reference – A security token, that is included in the message in the <wsse:Security> header, is associated with an XML Signature. The figure below illustrates this:

2341

2342

2343

Formatted: Font: 10 pt

Deleted: 15 March 2004

Formatted: Font: 10 pt

Deleted: 2004.

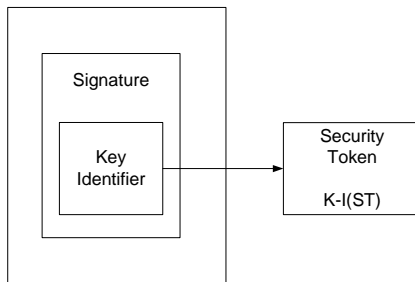

2344
2345
2346
2347

Remote Reference – A security token, that is not included in the message but may be available at a specific URI, is associated with an XML Signature. The figure below illustrates this:

2348
2349
2350
2351

Key Identifier – A security token, which is associated with an XML Signature and identified using a known value that is the result of a well-known function of the security token (defined by the token format or profile). The figure below illustrates this where the token is located externally:

2352
2353
2354
2355

Key Name – A security token is associated with an XML Signature and identified using a known value that represents a "name" assertion within the security token (defined by the token format or profile). The figure below illustrates this where the token is located externally:

2356
2357
2358
2359
2360

Format-Specific References – A security token is associated with an XML Signature and identified using a mechanism specific to the token (rather than the general mechanisms described above). The figure below illustrates this:

Formatted: Font: 10 pt
Deleted: 15 March 2004
Formatted: Font: 10 pt
Deleted: 2004.

2361 **Non-Signature References** – A message may contain XML that does not represent an XML
 2362 signature, but may reference a security token (which may or may not be included in the
 2363 message). The figure below illustrates this:

2364
 2365
 2366 All conformant implementations **MUST** be able to process the
 2367 `<wsse:SecurityTokenReference>` element. However, they are not required to support all of
 2368 the different types of references.

2369
 2370 The reference **MAY** include a *ValueType* attribute which provides a "hint" for the type of desired
 2371 token.

2372
 2373 If multiple sub-elements are specified, together they describe the reference for the token.
 2374 There are several challenges that implementations face when trying to interoperate:
 2375 **ID References** – The underlying XML referencing mechanism using the XML base type of ID
 2376 provides a simple straightforward XML element reference. However, because this is an XML
 2377 type, it can be bound to *any* attribute. Consequently in order to process the IDs and references
 2378 requires the recipient to *understand* the schema. This may be an expensive task and in the
 2379 general case impossible as there is no way to know the "schema location" for a specific
 2380 namespace URI.

2381
 2382 **Ambiguity** – The primary goal of a reference is to uniquely identify the desired token. ID
 2383 references are, by definition, unique by XML. However, other mechanisms such as "principal
 2384 name" are not required to be unique and therefore such references may be unique.
 2385 The XML Signature specification defines a `<ds:KeyInfo>` element which is used to provide
 2386 information about the "key" used in the signature. For token references within signatures, it is
 2387 **RECOMMENDED** that the `<wsse:SecurityTokenReference>` be placed within the
 2388 `<ds:KeyInfo>`. The XML Signature specification also defines mechanisms for referencing keys

Formatted: Font: 10 pt

Deleted: 15 March 2004

Formatted: Font: 10 pt

Deleted: 2004.

2389 by identifier or passing specific keys. As a rule, the specific mechanisms defined in WSS: SOAP
2390 Message Security or its profiles are preferred over the mechanisms in XML Signature.
2391 The following provides additional details on the specific reference mechanisms defined in WSS:
2392 SOAP Message Security:

2393
2394 **Direct References** – The `<wsse:Reference>` element is used to provide a URI reference to
2395 the security token. If only the fragment is specified, then it references the security token within
2396 the document whose `wsu:Id` matches the fragment. For non-fragment URIs, the reference is to
2397 a [potentially external] security token identified using a URI. There are no implied semantics
2398 around the processing of the URI.

Formatted: No underline

2400 **Key Identifiers** – The `<wsse:KeyIdentifier>` element is used to reference a security token
2401 by specifying a known value (identifier) for the token, which is determined by applying a special
2402 *function* to the security token (e.g. a hash of key fields). This approach is typically unique for the
2403 specific security token but requires a profile or token-specific function to be specified. The
2404 `ValueType` attribute defines the type of key identifier and, consequently, identifies the type of
2405 token referenced. The `EncodingType` attribute specifies how the unique value (identifier) is
2406 encoded. For example, a hash value may be encoded using base 64 encoding.

Deleted: (the default)

Formatted: No underline

2408 **Key Names** – The `<ds:KeyName>` element is used to reference a security token by specifying a
2409 specific value that is used to *match* an identity assertion within the security token. This is a
2410 subset match and may result in multiple security tokens that match the specified name. While
2411 XML Signature doesn't imply formatting semantics, WSS: SOAP Message Security
2412 RECOMMENDS that X.509 names be specified.

2413
2414 It is expected that, where appropriate, profiles define if and how the reference mechanisms map
2415 to the specific token profile. Specifically, the profile should answer the following questions:

- 2416
- 2417 • What types of references can be used?
 - 2418 • How "Key Name" references map (if at all)?
 - 2419 • How "Key Identifier" references map (if at all)?
 - 2420 • Are there any additional profile or format-specific references?

Formatted: Bulleted + Level: 1 +
Aligned at: 0.25" + Tab after: 0.5"
+ Indent at: 0.5"

2421
2422 This section is non-normative.

Notices

OASIS takes no position regarding the validity or scope of any intellectual property or other rights that might be claimed to pertain to the implementation or use of the technology described in this document or the extent to which any license under such rights might or might not be available; neither does it represent that it has made any effort to identify any such rights. Information on OASIS's procedures with respect to rights in OASIS specifications can be found at the OASIS website. Copies of claims of rights made available for publication and any assurances of licenses to be made available, or the result of an attempt made to obtain a general license or permission for the use of such proprietary rights by implementers or users of this specification, can be obtained from the OASIS Executive Director.

OASIS invites any interested party to bring to its attention any copyrights, patents or patent applications, or other proprietary rights which may cover technology that may be required to implement this specification. Please address the information to the OASIS Executive Director.
